8.a. B: If I persist in using my terminology in the matters of dogs and wolves, I suppose we still can communicate.

9.a. A: Sure. You will just add another ambiguity within our language community.

III

As in (I) except for the following changes:

5.b. A: No, I do not think Peter has those characteristics. It has the following: . . .

6.b. B: If that were the case, I agree that Peter would be a dog.

7.b. A: If it had the set of characteristics you mention, I would agree that Peter is not a dog.

I shall try to show that the searching (zetetic) sceptic need not cause more trouble to a linguistic community than Mr. *B* in the community *C*—that is, only very common kinds of trouble; slight trouble because of some divergences regarding vocabulary.

The pressure to conform in opinions and terminology may be heavy in small communities with close personal ties. At least, this is what some of us think was the case in rural Scandinavian communities of the nineteenth century. Today, we favor a more lenient treatment of people with odd vocabularies. Zetetic sceptics, I think, are today accepted as members of their communities. They are not thought by ordinary people to have left their language community. They are understood, perhaps inadequately, as

are many other marginal groups, but sufficiently to keep communication going.

Are there zetetic sceptics among very young people? I came across two or three when I interviewed some 250 people about truth and knowledge. The youngest was only fourteen years old but very clear in his spontaneous answers. He clearly distanced himself from “Academic” sceptics, in the terminology of Sextus. He did not reject the possibility of knowledge and finding truth, but he had never come across any. That the Earth is round he did not find to be an established truth. Nor did he regard the Academic sceptics’ rejection of the possibility of knowledge to be established.

There are, I hope, a few communities that never abstain from using “I know that . . .” because they feel sure of a remote possibility of being mistaken. Sometimes the responsibility for saying “I know that . . .” makes one look for remote possibilities. If the existence of such possibilities seems sure, most people will abstain; some will not. Anyhow, there is no limit such that if remoteness is still greater the *language* community prescribes the use of “I know” or the answer “I know” if one is *asked* “Do you know?”

Innovation in a community is largely dependent on some people taking seriously possibilities that others judge nonexistent or completely negligible. Language functions satisfactorily in allowing us to communicate in spite of extreme personal differences in judging possibilities.

A zetetic sceptic feels sure or unsure about remote possibilities of error in relation to the knowledge claims he has witnessed. He does not deny that he may often be linguistically, or better, socially, justified in accepting such *claims* as legitimate. The social and linguistic *warrant* to use the phrase “I know that . . .” is for him not a sufficient reason actually to use it. When he feels that there are remote possibilities of error, he will, perhaps, use such a phrase only in certain kinds of practically important situations, such as in law courts.

Rescher’s position leans in a decisive way upon differences between remote and near, or unrealistic and realistic, possibilities of being mistaken. In heavy urban traffic the distinction is decisive, but not always in philosophy.

As a believer in the importance of dialogues in assessing scepticism, I invite the reader to inspect some examples.

ZETETICISM

I

A: Sometimes when engaged in painting I long to develop into a Picasso of the twenty-first century.

B: But you know you will not.

A: How do I know? The future is open.

B: You agree that it is only an extremely remote possibility.

A: Yes.

B: Then you know.

A: Really? What process do you refer to?

B: By just adhering to the basic rules of your language community, the laws of rationality, and submission to the facts of life.

A: Usage is richer and the laws of rationality less narrow than you assume! I abstain from using the expression “I know” when I feel there is even an extremely remote possibility of error.

B: I’ll remember your strange abstention. We can continue our excellent communication.

II

1. A: Open the package here. Let us admit, though, that it may in principle contain a bomb that will explode if we do so.

2. B: I know there is no bomb in it.

3. A: But there is a remote or unrealistic possibility. . . .

4. B: Certainly. Therefore I repeat: I *know* there is no bomb in it.

5. A: Under the circumstances you do *not* know—that is, according to my usage.

6. B: You leave our language community if you say you do not know.

7. A: I would not say *you* leave the language community by saying “I know,” but that your talk is a little queer if you say “I know there is no

bomb in the package, but there is an extremely remote and unrealistic possibility that there is a bomb in it.”

III

As in (II) except for the following changes:

4.a. B: No, I do not think there is any possibility, remote or near. If I thought there were, I would not have used the expression “I know,” and I would not have agreed to open the package.

5.a. A: Well, we disagree about possibilities, not about how to use “I know.”

6.a. B: Yes. You have not left our language community.

In the communities I am acquainted with, the position of *A* in dialogues II and III is rather unusual. If a possibility of being mistaken is explicitly admitted, one tends not to say one knows. One does not have an “adequate rational warrant” to combine a claim to know that *p* with a claim to know that not-*p* may be true. One may elaborate upon the remoteness and unrealistic character of the possibility. Nothing is lost from the point of view of (cognitive) communication. The elaboration may have the same effect—to induce *action* according to plan: “the possibility of a bomb seems so remote that we agree to open the package.”

Dialogue III is of a rather common kind in communities with which I am acquainted. Clear consciousness of a possibility of mistake disqualifies the use of “I know . . .,” or: if people believe in a concrete possibility of error, they do not use “I know” except for performative purposes. If you ask how I as a mild sceptic know all this, I will answer with Sextus that this is how it seems to me. I may be in error, but I adapt to my community’s way of talking and therefore do not use the term *seems* all the time.

Consider the case of Paul, who was labeled a zetetic sceptic by members of community *C*. In the local newspaper of *C*, in an obituary, a journalist wrote, among other things:

When hunting, Paul saw all kinds of remote possibilities—what kinds of animals we would encounter, even what kind we actually had shot. It was as if he lived in a vast number of different worlds, and was not very eager to decide which one was ultimately the real one.

ZETETICISM

He did not find it difficult to act. He was not a “dreamer.” However, he clearly did not feel deeply certain about the actual features of the situation in which he acted, or about his own ultimate identity. He did not understand why we were so eager to proclaim that we *knew* this or that, or that such and such was *true*. He seldom was inclined to disagree, because he did not find it important to know the details of what we meant by words like “truth” in our declamations. We agreed that if he clearly saw possibilities of mistake, or believed he saw them, he had better abstain from asserting truth and knowledge. He, on his side, did not find that *we* should abstain when we did not clearly see possibilities of error. He did not criticize our usage.

If Paul thought he (1) saw possibilities of mistakes every time he consciously looked for such possibilities, and (2) often was interested in the elimination of mistakes, and (3) “undogmatically and loosely” uttered things like “Do I know anything?” and “How do I reach truth?” then Paul was a zetetic sceptic. (Compare Sextus *PH* I, section 187, et seq.)

Paul did not enter into “a self-imposed exile” from the language community. He certainly was an odd member of the community *C*, but he communicated well. His vocabulary and use of each word was exceptionally conventional.

The authors of the obituary implicitly hold that if they had felt as Paul did, they would have abstained from making the usual knowledge and truth-claims.

Finally, I shall introduce an odd member of a community *D*. He was a teacher of philosophy. When he died, a student wrote:

When I first met Alastair he was an ardent Christian, insisting that all things in every life situation were colored by his faith, and that color was of reality, not of subjective appearances. “Let us eat dinner together!” had a different meaning for him than for those without his particular faith. Meals were sacred. A glass of wine, even a grain of sand had a particular reality as a creation of God. A moment’s lack of appreciation of this reality was to him a moment of sheer blindness or lack of understanding.

Later, however, his work made him at home in different cultures. He met Christians who seemingly had a different total view in spite of using the same biblical texts as a source. He met Buddhists and people of religious and philosophical faiths that either seemed to imply the existence of different basic presuppositions or implied a denial of the relevance of some of his own. His belief was as firm as ever, but he was shattered in his former assumption that he could defend basic assumptions of his faith in terms of knowledge. Moreover,

because his faith was pervasive, and colored all his assertions, this seemed to him to imply that he could not assert flatly that he *knew* he was right and that those with different total views from his were simply mistaken. So, *he withdrew his claims to knowledge.*

When he died he was still trying to make clear, or at least to make conscious, presuppositions that he only dimly felt he had acted upon in his long life. Once in a seminar somebody exclaimed, "But Alastair, you are a zetetic sceptic!" He seemed slightly embarrassed, but after listening to explanations, he very tentatively agreed. The term *sceptic*, in its modern connotation, he found somewhat misleading, however.

The account of this student exemplifies a zetetic scepticism that perhaps can only be appreciated if we try to incorporate all our assertions into a total view, religious or philosophical. If this is done in such a way as to make the validity of any assertion dependent (but not *only* dependent) on a set of basic principles, we get into the old aporetic or paradoxical area of comparisons of total views. This seems to lead to the zetetic scepticism of Alastair if our personality is integrated to such an extent that consciousness of the dependence of our particular assertions on our total view is never completely lost. We are then beyond the knowledge/ignorance distinction, because of the deepness of premises questioned, and the pervasiveness of implications. Some might (with a smile?) call it bathyscopic agnosticism rather than zetetic scepticism.

Sloppy-Talking Sceptics

Let me come back to the mild ways of the zetetic sceptic—his lack of motivation to change the loose talk among his fellow citizens.

All through Sextus Empiricus's *Outlines of Pyrrhonism*, he suggests that he does not fight for or against definite usages of words. He does not have any special motives in ordinary social life to be more painstaking in his way of talking than other people are. He may use loosely such expressions as "I know that . . .," "it is true that . . .," "evidently," and "of course." He may also make use of all the performative functions of these expressions. Consider this little story:

John has been regarded as a zetetic sceptic, but what about his verbal behavior in a recent law case:

ZETETICISM

John: I know Jack was in bed with stomach trouble and a broken collarbone all that Wednesday, so he could not have murdered James.

A: Is it not at least remotely possible that Jack was in bed only the first half of Wednesday?

John: No, no. That is not possible. The evidence available excludes that possibility. I know he was in bed *all* Wednesday.

In John's next seminar on epistemology, his students complained of a discrepancy between life and teaching. His answer: "I consider myself a close friend of Jack and feel it is my duty to defend him in court. With the evidence at hand I was, I think, fully entitled to use the term *know*. If I had said that I did not really know, this would have been misunderstood. I followed the usages of my community. In regard to the possibilities, I felt that there was no serious practical possibility that I was mistaken. I am known as a friend of Jack's, and if I had said, 'There is a remote possibility I am mistaken,' it would, I think, have been completely misunderstood. Here in this seminar, the dialogue is of quite a different kind. I would here answer very differently from how I answered in court."

The students were still not quite satisfied. John's eagerness in explaining his behavior made them suspicious: "Your explanation is full of assertions, of sentences pretending to be true?" John's answer: "This sounds strange to me. Does eagerness imply pretentiousness of that kind? May I not speak eagerly but adogmatically, in the terminology of Sextus?"

Tentative conclusion: John is a zetetic sceptic. He talks in a manner that makes me trust the honesty of his particular way (Sextus: his *agogé*).

If the dogmatic attitude revealed itself, and *only* revealed itself, in the use of the terms *know* and *truth*, one might—as some have done for years—simply abstain from using them. There are, however, expressions like "it is the case that" and hundreds of others that are in the same class. Ultimately, all simple assertive use of language is involved, including, of course, assertions like "It *is* uncertain that . . ." and "It *is* scarcely a remote possibility that. . . ." The *thoroughly* inquiring way of the zetetic sceptic can be hinted at through dialogues, but one cannot expect a zetetic sceptic to describe it through assertions. The zetetic sceptic may try to convey this by saying that he talks loosely.

If, however, a dogmatist asks him for once to talk very seriously, to be painstakingly precise and describe his exact position in epistemology, what

can he do? Answer, “I am inquiring?” (*zeteitos*). That is a rather vague and loose answer, but the more precise he makes the answer, the more clearly he involves himself in typical “dogmatic” utterances. He is tempted to interpose expressions like “perhaps,” “it seems,” “I think,” and so on, but this implies that he only then reverts to loose talk.

The moderate difficulties of communication between zetetic sceptics and dogmatists are only an instance of the difficulties of different total views. The more strictly total they are, the more difficult is straightforward clarification of the difference. The meaning of every sentence has different colors within the different totalities.

Fortunately, the resulting limitation of communication does not necessarily affect the community. People with different total views *may* have a good time together, talking or not talking. In a society there are “standards that govern its practices. To refuse to countenance what *they* call knowledge as *my* ‘knowledge’ is as serious—and deviant—as to refuse to countenance what *they* call dogs as deserving of this appellation from my variant point of view” (Rescher 1980: 74). If I “choose to be more scrupulous than the language using community,” I enter “[to this extent] into a self-imposed exile from it” (*ibid.*).

It is strange to realize, after more than eighty years of speaking, that I have lived in exile from my community. As far as I can judge, some of my friends have suffered the same kind of exile. However, it does not seem to have been like this—especially not when there is a question of being *more or less* scrupulous, and especially when my fellow beings become aware of my deviation only when we enter philosophical discussion. What in the terminology of Rescher seems to be classed as difference in degrees of scrupulousness, is, in my and Sextus’s terminology, classed as difference in degrees of looseness.

Do Zetetic Sceptics Ask for Guarantees?

Do the zetetic sceptics ask for the impossible? It seems that Rescher may have this suspicion (see Rescher 1980: 75, 226). Consider, however, the following dialogue:

ZETETICISM

A: You say you don't know that there is no bomb in the package because you see a remote possibility that there is. What if you did not see any such possibility?

B: Then I might say "I know."

A: Do you always see possibilities for error?

B: Not *immediately*, but I have upon reflection always seen such possibilities. This probably has contributed to my tendency to avoid "I know," even if a discussion is not serious and responsibilities not heavy. Sometimes, though, I spontaneously say "I know!" "Certainly!" "True!" I do not fight against spontaneous utterances. I speak loosely.

A: Then you are occasionally and momentarily a dogmatist!

B: Ultimately, what counts is what I mean, not what sounds I make. I retreat from the use of those terms if asked, "Do you really, seriously speaking, *know*?" I retreat because I am made to consider possibilities of mistakes. Do not philosophical views rely on reflection?

A: Are you still on the lookout for positions that you cannot see could possibly be mistaken?

B: Yes, but it is no longer a question of life and death to find such possibilities. It is just one of my interests. Take, for example, my interest in logic and formal systems. Are they true in some sense? I am not worried, however. I have reached a satisfactory level of *ataraxia*, peace of mind. My scepticism is of a joyful rather than a sad variety.

A: You are looking for the impossible. There can be no views that are not possibly mistaken.

B: That seems to be the position of the *Academic* sceptics. Maybe they are right, I don't know. I have not seen a convincing argument.

A: You require the impossible when you refrain from using the expression "I know that. . . ."

B: What you say is interesting, but I do not know of any such requirement. If we meet again next year, perhaps I will, after due reflection, use that ex-

pression. I may next year have convictions that, in spite of long reflection, I cannot possibly see might be false. Perhaps I will end up as a Heraclitean. . . . Some zetetic sceptics do.

A: What you admit now is that you have no philosophy, only tentative autobiographical opinions.

B: If you insist! Why, though, do philosophers argue against me? What you say seems to imply that a philosophy *must* be dogmatic. You may be right, but I think of myself as an undogmatic philosopher.

The Rational Warrant to Say “I Do Not Know” or “Do I Know?”

Suppose there is a *social* warrant for asserting “I know . . .” in a particular situation. It seems that Rescher assumes that this implies that there is no *rational* warrant in this situation for saying “I do not know.” Let us look at the following dialogue:

A: I know the gun is not loaded.

B: Your responsibility is heavy. Check it!

A: Specify the possibilities that this gun at this moment is loaded!

B: I cannot at the moment see any definite possibility.

A: Then you know it is not loaded.

B: I am sure that it is not loaded, but we have not checked it for ten minutes. I don't *know* that it is unloaded at this moment.

A: I'll try it out. (Bang!) Sorry. I'll get hold of an ambulance and all will be well, I hope.

Even in this case, in which no definite source of error is seen and the possibility of being mistaken is conceived as remote, I would say that we have a rational warrant for asserting “I do not know . . .,” using the word in a strict sense. Otherwise, I would in my opinion here and now implicitly subscribe to a concept of petty rationality conducive to conformity or *Gleichschaltung*. Respect for reason seems to me incompatible with the de-

nial that remote possibilities, even astronomically remote possibilities, may be relevant for knowledge claims. Social and cultural diversity rests not only on tolerance of wide differences of opinion, but often on promoting them.

Differences of opinion regarding possibilities are in practical matters crucial. What in one group is an extremely remote possibility is a very near one in other groups. Usually only a minority is aware of definite possibilities of error because this awareness presupposes lively interest and a surplus of energy. The sloppy textbook and administrative use of "It is known that . . .," "Today we know that . . .," and similar persuasive expressions has the potentially destructive effect of making people submissive. This may happen in spite of occasional warnings that even scientific knowledge is uncertain. Important alternatives in individual, social, and political life are neglected because of stiffening terminology.

Perhaps the expression "socially warranted claim to know" is better than "rationally warranted claim" because of a fatal tendency to equate rationality with what is considered "reasonable" within a group of opinion leaders. I think it worthwhile to try to save the term from such a debasement.

Rescher maintains a strange view about my view of knowledge claims:

In Naess' view, our knowledge claims are inherently flawed, because—as he sees it—the achievement of knowledge requires the prior removal of *both sorts* of possibilities, as well as the merely proximate ones. This, of course, leads straightaway to the sceptical conclusion that the attainment of knowledge becomes in principle infeasible. Thus Naess writes:

[The] incorrigibility claims [inherent in our pretensions to knowledge] are essentially based on convictions that in the particular case there could not be any source of error, both in the usual sense of "source of error worth mentioning" *and in the sense of no source of error even of the more remote kinds that we neglect in daily life.*

(Rescher 1980: 88)

In my view, there are socially unjustifiable and socially justifiable knowledge claims. To withdraw a claim, however, means to acknowledge that we did not know what we claimed to know, and this frank admission is completely independent from the remoteness of the possibility that the claim will turn out to be a mistake. "The accused tested the gun repeatedly. He

was fully justified in saying that he knew it was unloaded, but, alas, he was wrong. What *seemed* impossible happened.” I am not for a completely new social practice. Sometimes our claims are irresponsible, but often it would mislead if we, being asked, were to say “I don’t know.” The incorrigibility *principle* says that we go against the strict use of the term *knowledge* if we say “I *know* that such and such, but there are remote possibilities that I am mistaken,” that is, remote possibilities that I don’t know that such and such.

Let us now look at the following inference.

Premise: Knowledge that such and such, implies absence of possibilities, remote or proximate, that such and such is a mistake.

Conclusion: Knowledge that such and such is in principle (absolute) unattainable.

There are no formal logical rules such that the conclusion follows from that premise. One must add one or more premises. From “I don’t see how I can avoid the *possibility* of a mistake” does not follow “Avoidance of such a possibility is never possible.” The situation does not change if “no one sees” is substituted for “I don’t see.”

I completely agree with Rescher, though, when he says: “Knowledge claims impose no inherently infeasible demands. The ‘incorrigibility’ of our knowledge claims require no more than that every *realistic* prospect of error has been eliminated” (Rescher 1980: 89). Claims do only impose mild demands—no realistic prospect of error from a social point of view. “You, as an adult member of our society, should have made more inquiries before you claimed to know. There was a perfectly realistic possibility of a mistake.”

My general conclusion here is that what Rescher says does not substantiate that the Pyrrhonic sceptic as conceived by Sextus in any way leaves the linguistic community when he supports the strict concept of knowledge and *refrains from using the term* except when loose use of it is socially required.

One of the serious arguments against the existence of zetetic *philosophers* as characterized by Sextus may be formulated as follows: If a zetetic says something like “I do not think I have ever found any truths or possessed any piece of knowledge, but I am still inquiring,” his testimony is interesting as a fragment of an autobiography. It does not deserve the name

of philosophy. If, on the other hand, he positively asserts that he has not found, or that it cannot be found, he is no longer a zetetic. If he lets us understand that he is speaking loosely, he does not speak as a philosopher. In this case he might be said to join the cultural conversation in a postmodern sense, but not to be engaged in the exposition of a philosophy. Conclusion: there may be zetetics, but there are no zetetic philosophers. Philosophers don't speak loosely!

The above conclusion is warranted, I think, as long as the philosophy of a zetetic sceptic consists only of one epistemological point, the zetetic point. He may, however, be working within the framework or tradition of any philosophical system or tradition, not just the Heraclitean or other sceptical-sounding traditions. He may even work within Platonic, Scholastic, or Spinozistic *traditions*. To try to work and act within a definite framework, one has to *accept it tentatively*. The acceptance needed is not acceptance as knowledge, or truth.

Sextus proclaims (Pyrrhon., 1,1,1) the distinction between dogmatists and sceptics in order to present a main classification of philosophers. Other *fundamental divisions* deserve our attention, but considering other divisions does not undermine the one that Sextus makes.

Always on the Way

The human mind is an inquiring mind. When deeply engaged it pursues a mercilessly thorough inquiry. Nothing is left untouched, not even the sense impressions, not even logic. At any moment, though, the focus of attention is limited; therefore, we must work with presuppositions we neither firmly believe nor momentarily question. The more precisely we formulate the specific question we focus on, the clearer is our awareness of the questionable assumptions we accept in order to formulate that particular precise question. With a change of focus, any of these assumptions may, it seems, be questioned.

Nicholas Rescher, in his meticulously fair but critical survey of arguments, reminds me of the human inability, whether desirable or not, to live continuously engaged in questions regarding inquiry into deep premises of thinking, premises of our own actions and our own way of life. This inability may be a "fact of life," or maybe it is not. It may make it insincere to

Trust and Confidence in the Absence of Strict Knowledge and Truth

avoid expressions like “I *know* that . . . ,” and “It *is* true that. . . .” I am not sure about this inability, however. Perhaps even some of those who often use the expressions freely, even sloppily, do have continuously an awareness of undecidedness and a persistent desire for further inquiry. Some searching souls are perhaps sufficiently integrated to live *consistently* the life of a conscious, vigilant, searching, joyful sceptic.

How Can the Empirical Movement Be Promoted Today? A Discussion of the Empiricism of Otto Neurath and Rudolf Carnap

Preface, 1956

This little treatise was written in the years 1937–1939. At that time logical empiricism as a philosophical movement was hardly known here in Norway. Today there are many who not only know about it but who have studied it more or less carefully. These circumstances are part of the reason that I did not want to publish this paper before the war, whereas I now consider the moment suitable for publication.

This essay concerns the logical empiricism of the 1930s. The authors discussed have since modified their opinions in several respects. This is particularly true of Rudolf Carnap. I believe the treatise may nevertheless contain something of interest. Carnap has already become a “classic.” A discussion of his viewpoints, at whatever phase of his production, benefits the general interest. Added to this is the fact that the treatise represents a

This paper, originally written in German during the years 1937–1939, was made accessible as a mimeographed semipublication in 1956 by the Institute for Philosophy and the History of Ideas, together with Universitetsforlaget in Oslo, under the title *Wie fördert man heute die empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolf Carnap*. This (authorized) English translation of the German text is by E. M. Barth. The editors warmly thank Mr. H. Isaacson for his suggestions for improving the English. Footnotes dating from 1939 are indicated in the usual manner. The numbers between brackets refer to the notes and comments in appendix I that were added by Naess in 1956.

This article was reprinted with permission from *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. van Dormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), 197–255.

kind of empiricism that even today differs from the usual sort, an empiricism “without dogmas” and with “research,” not “science” (scientism), as its central slogan. I hope soon to have the opportunity to discuss from the same point of view some of the schools that have evolved more recently with analytical and empirical tendencies, in particular, the so-called Oxford philosophy.

By means of notes and comments (see appendix I, page 198) I have tried to link the treatise with the problems that command particular interest today.

I owe sincere thanks to Cand. jur. L. Porsholt for the considerable interest he has shown in this treatise and for verbal and stylistic improvements to the manuscript. He also took care of the translation (into German) of the two appendixes, which were originally written in Norwegian.

There Are No Universally Valid Demarcation Criteria

In textbooks on the history of philosophy, positivism and empiricism are discussed as certain doctrines among other philosophical doctrines. By means of abstract and often unclear concepts like ‘data’, ‘facts’, ‘experience’, and ‘science’, short and elegant formulations are made up that supposedly “define” empiricism and positivism. [1] [Numbers in brackets refer to appendix I.] These definitions are intended to serve as demarcation criteria (*Entscheidungskriterien*, decision criteria) that allow for a classification of the various doctrines, as is usual in the history of philosophy. One should be able to distinguish “criticism” from “empiricism,” “pragmatism” from “Bergsonism,” and so forth. The question arises of whether one can regard these formulations as adequate without completely disregarding the actual, ordinary uses of language. Through these formulations the empiricists, so to speak, meet the metaphysicians on their own ground: the empiricists offer formulations that are hardly inferior in abstraction, generality, and ambiguity to the acknowledged metaphysical formulations. I sympathize with those who, given these definitions, are neither empiricists nor positivists and who thus have to rank as metaphysicians. I agree with the metaphysicians in decisively rejecting the doctrines that one is supposed to accept in order to be a true and real empiricist. One renders the antiempiricists a good service when one defends such points of view.[2] In

the first place, one leaves the field of scientifically defensible formulations; in the second, one remains stuck with assertions that—insofar as they are a kind of negation of metaphysical points of view—have a meaning only as contraries to the latter and do not represent any independent contribution.

One of the merits of the logical empiricists is to have brought about a break with tradition on this point. The first steps toward emancipation from the scholastic mode of discussion have already been taken, and the unique capacity for development of the logico-empirical orientation guarantees that other steps will follow. I believe that with my proposals for changing formulations for the logico-empirical attitude, I am in accordance with the intentions of the triumvirate Carnap, Frank, and Neurath—but perhaps I am wrong.[3] In any case, many of their formulations seem dubious to me. To discover how the various formulations of this triumvirate are to be understood, I shall in the following pages choose a polemical style whenever this seems to me to serve the purpose.

There are some people who, though not always preoccupied with the special problems of any of the highly developed sciences, refer more frequently than other people do to the statements of so-called scientists and who in matters of ideology as well prefer to subscribe to the opinions of scientists rather than to those of other population groups. Whether the non-verbal behavior of such people has certain common characteristics is a question that may be left open; this problem belongs to characterology and to the “study of the behavior of intellectuals,” as Neurath called it.¹ In any case, I assume that certain linguistic habits occur more frequently and with a stronger positive emotional coloring among scientists than in other groups, and that utterances such as “He is an empiricist,” “He does not tolerate speculation in these matters,” and “He leaves it to future research to come to a decision here”[4] are used more often to refer to scientists than to other people.

Since terms like *empiricist* belong to ordinary language, and I assume (though I may well be mistaken) that the class of people who definitely count themselves as empiricists includes the class of people who have the attitude that I call empirical, I shall retain the word *empiricism* and state a number of theses and programs regarding the “empirical attitude.” If someone finds these theses and programs unacceptable, then there are two possibilities: either the two of us use the word *empirical* about different and

partly contrary attitudes, or he regards the thesis as not quite appropriate for that attitude, as exemplified in certain individuals, that we both call empirical. My first thesis is as follows:

1. Given a class of sentences, some of which are compatible with the empirical attitude and others of which are not, there is no decision procedure (*Entscheidungskriterium*) allowing of a short formulation (in, say, fewer than 1,000 words) that can be applied to distinguish those sentences that are compatible with the empirical attitude from those that are not.[5]

By stipulating that the criterion must not be too comprehensive, I eliminate the possibility of enumerating, in formulation of the decision procedure, all those sentences of which one—with a certain probability—can assume that they are regarded as “incompatible.” History teaches us that certain examples always recur.

When I say that there is no decision method, I only mean to state the untenability of the decision criteria that are at hand, not the “impossibility in principle” of formulating such a criterion. At any moment, one can find certain problem areas within which the discussion about what is compatible with empiricism is carried on with particular fierceness and scope by participants of high reputation. One discusses, for example, how seriously one is to take certain theoretical constructs such as “atom,” “*n*-dimensional space,” and so on, when one wants to make physical statements by means of them. Then there is the discussion about whether psychoanalytical theories can be accepted within the framework of the empirical attitude. Certain unverifiable assertions make for a wider area of debate. Assertions of this kind, of which even their advocates admit that they can neither be strengthened nor weakened within a finite period of time, are made. Is the admission of such assertions compatible with the empirical attitude?

It may seem that it would be much easier to set up a decision criterion of the said type when the class of sentences concerned in thesis 1 is limited to a certain field of discussion than when no such limitation is undertaken. However, to my knowledge such a decision has not as yet been found for any concrete field of problems.

The contributions one hopes for from such a decision criterion can, however, be reached in other ways. I offer the following thesis:

2. Within a given area of debate it is practically possible to sum up certain groups of assertions that empiricists regard as antiempirical by means of suitable formulations. Furthermore, it is possible to come to an agreement to avoid these assertions until further notice—to start with, in the area of debate in question; second, in any area of debate.

Even if only a small number of contested assertions could be neutralized in this way, it would help to promote the empirical movement.[6]

There are decision criteria that have been frequently applied, and often successfully, such as the criterion of verifiability of the Vienna Circle. By demanding from an opponent in a discussion that he must state the conditions under which his assertion is to be regarded as verified, and the conditions under which it should be regarded as falsified, one often enforces a certain concretization like that which the pragmatists obtain by means of a related discussion technique. The Bridgman method of asking for “operations” has become very popular (Bridgman 1927, 1934). A concretization usually requires an empirical formulation of the problems; it gives a direction to the discussion that makes it easier to bring to the fore the empirical component of the standpoint. If, on the other hand, the decision criteria—for example, statements about verifiability or, to use a term from Carnap’s recent publications, “reducibility” (Carnap 1936a, 1936b, 1937)—are elaborated to doctrines and defended as theses, then one constructs an unwieldy theoretical superstructure above practical and expedient technical instruments for discussion, and thereby weakens the empirical position.

The same holds for operationalism. In *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge Acquisition and Scientific Behavior), I have tried to point out the weaknesses of an “operational view” that is presented in the heavy armor of a general doctrine.

When the decision criteria that are presented in the form of theses are replaced by proposals for the technique of discussion, in given areas of debate, they lose their external dignity but they gain in efficiency. This observation leads to the following thesis:

3. It is practically feasible, in connection with assertions occurring in given fields of debate, to set up certain general demands by which the elimination of nonempirical formulations is facilitated. Such

demands may be regarded as technical instruments for empirically oriented discussion and exposition.

Should anyone be of the opinion that such a demand ought to be universally valid for every sentence compatible with the empirical attitude, or that it be anchored, for example, in the “Logic of Science,” then it would be desirable to distinguish this opinion from those according to which this demand may promote empiricism as an instrument in discussion. One then would have a technique for discussion in common and disagree only as to the import of these demands when they occur in the form of statements about statements.[7]

Carnap’s and Neurath’s Demarcation Criteria: Physicalism

Many physicalist formulations seem to me speculative. Popper has called physicalism “metaphysical.” That seems to me to be merely a polemical sharpening of the situation. The question I want to discuss below is not whether physicalism, version 1936–1937, is antiempirical but whether it proves useful. It then becomes important how one interprets it. The presentations of physicalism are extremely brief compared with the enormous pretensions that they represent.² One does not quite know how to interpret physicalism in detail.

For the following analysis I have to choose whether to interpret physicalism in a very benevolent manner or to stick more closely to the available formulations of it. I choose the latter. It would be a demonstration of a particular disdain for physicalism were one to agree with its adherents only because one had the feeling that they were working for the same general goals as oneself and because one therefore had a “positive transference” in readiness. It also may be seen as a characteristic feature of the writings of Carnap and Neurath that they culminate in concrete formulations that are supposed to stand on their own feet.

What brought Neurath to set up the first formulations of physicalism? According to his own statements (Neurath 1936c), it was the conviction that one could (and, we add, that one should) discourse about stars and about human beings with the same “logical technique” and in the same scientific, unexalted—and for Neurath that means unmetaphysical as well—way. Who-

ever has such a feeling will enthuse about physics as a lover of art may enthuse about particularly outstanding works of art. One may well recognize the limitations of the scientific achievements of the physicists and dissociate oneself from the *philosophizing* physicists; something will nevertheless remain that may serve as a model for research workers in fields other than physics. Hence, the frequent attempts to imitate the physicists, to use their terminology, to carry their questions over to biology, psychology, and sociology. [8] These attempts probably do not originate so much in the conviction that physical doctrines are directly applicable to these fields as in the feeling that the physicists' fundamental attitude and their working methods, which have been corroborated over a long period of time through a series of scientific investigations, will be more easily carried over to other fields when something of the external equipment of physics is brought along at the same time.

The formulations of the nineteenth-century materialists mostly portray very crude and strongly ideologically impregnated attempts to carry out this transfer. Since those attempts reflect their predilection for the more metaphysically-ontologically colored physical theories, they are completely valueless today when taken as expressions of a basically scientific attitude. Neurath wanted to find a formulation that could measure up to the high standards of advanced research into foundations, of a theoretical physics understood as being in the process of undergoing deep changes, and of a discussion technique sharpened by the rise and dissemination of the new logic. I believe that the first formulations of physicalism should be evaluated from the point of view of this goal.

The goal is a high one, and I believe that one would have to be extremely generous to take the first formulations seriously. Carnap and Neurath are, however, absolutely prepared to regard these formulations as attempts that have been outstripped by formulations from recent years. Are those later formulations now to be regarded as improvements of the former ones on essential points? One might suppose that the changes have been made only under pressure from criticism and that they therefore are of a negative, unfruitful kind. I believe that such a supposition would be mistaken. The formulations have undergone a profound development, and the readiness to start anew and to admit earlier weaknesses does the physicalists great credit. This readiness is a much better guarantee of their basically scientific attitude than are their keenest formulations.

Let us declare, then, so as to simplify the discussion, that the older formulations of physicalism—say, until 1935—are to be regarded as “null and void.” It may nevertheless be worthwhile to take a closer look at them. Perhaps the line of development that connects these formulations with the current ones can be extrapolated so that it may give us an indication of how to develop the physicalist formulations still further.

In the domain of German culture, questions that do not uniquely belong to one of the special sciences are largely in the hands of members of the philosophical schools. The first formulations of physicalism were characterized by opposition to the view that such questions must be left to metaphysicians with or without a scientific education. German scholars were accustomed to the idea of acknowledging an authority over and above the sciences. This had led to an outlook on philosophy as a science with whose results the achievements of the special sciences must be in keeping in order to be “true,” and to which all questions belong that are not yet really dealt with by any special science. When physicalists say “There are no philosophical sentences,” this is a somewhat breezy expression of their rejection of this philosophical authority. The very strong position of professional philosophers, and especially their strong tendency to isolate themselves vis-à-vis science, is specific to the German culture. The sharp counterformulations (*Abwehrformulierungen*—the expression is Neurath’s) against the metaphysicians lose much of their point when they are used, say, within the English culture. A great weakness of the original formulations of physicalism is that they are much too clearly inspired by the wish to ward off a strong enemy who threatens to press the physicalists in their isolation against the wall. Under the influence of empirically oriented investigators from outside Germany, the physicalists could permit themselves to speak more freely. They became inclined to replace antimetaphysical formulations that were influenced by “local” feuds with ametaphysical ones. This replacement must, I believe, lead to the dissolution of the decision criteria that are formulated as theses. They have the important property in common with the counterformulations of having clear meanings only as negations of metaphysical utterances. When one asks for further content, they turn out to be ambiguous and hardly testable.

We now want to consider the most recent formulations of physicalism. The latest comprehensive formulation I know of comes from Carnap:

The so-called theses of physicalism assert that every term of the language of science—including besides the physical language those sub-languages which are used in biology, in psychology and in the social sciences—is reducible to the terms of physical language.

(Carnap 1936a: 467)

It will be necessary to analyze the terms *language* and *reducible* more closely. What does Carnap mean by these words?

Carnap's Term *Language*

To those unfamiliar with the special linguistic tenets of the physicalists, it will sound somewhat strange to hear about a “language” of science. Does science have a language of its own? To answer this question one has to investigate in more detail how Carnap uses the term *language*, for among physicalists *language* is a technical term, just as *world* is a technical term in Minkowski's publications or *Kapteyn universe* is a term among astronomers. In the English, and most recent, edition of his *Logical Syntax of Language*, Carnap comments on the term as follows:

(S1) By a language we mean here any sort of calculus, that is to say, a system of formation and transformation rules concerning what are called expressions, i.e. finite, ordered series of elements of any kind, namely, what are called symbols.

(Carnap 1937: 167)

(S2) In the widest sense, logical syntax is the same as the construction and manipulation of a calculus; and it is only because languages are the most important of calculi that, as a rule, only languages are syntactically investigated.

(S3) When we maintain that logical syntax treats language as a calculus, we do not mean by that statement that language is nothing more than a calculus. We only mean that syntax is concerned with that part of language which has the attributes of a calculus—that is, it is limited to the formal aspect of language. In addition, any particular language has, apart from that aspect, others which may be investigated by other methods. For instance, its words have meaning; this is the object of investigation and study for semasiology. Then again the words and expressions of a language have a close relation to actions and perceptions, and in that connection they are the objects of psychological study. Again, language constitutes an historically given method of communi-

cation, and thus of mutual influence, within a particular group of human beings, and as such is the object of sociology. In the widest senses, the science of language investigates languages from every one of these standpoints; from the syntactical (in our sense, the formal), from the semasiological, from the psychological, and from the sociological.

(Carnap 1937: 5)

From this it is fairly clear that “language” for Carnap consists in a system of rules, meaning not primarily in, say, a vocabulary and a grammar. The “expressions,” a subclass of which are “terms,” belong to a definite language only insofar as they are mentioned in certain rules. This is probably the sense in which the term *language* should be understood in the paper “Testability and meaning.”

The “language of science,” then, means a system of rules for the expressions occurring in science. Since such a system of rules has not been produced, I draw the conclusion that “rule” in Carnap’s writings is not always replaceable by “historically present, explicitly formulated rule.” Also, by “system” he can hardly mean “elaborated system”—for such systems exist only within metaphysics.

Certainly there are expressions that could be counted as “explicitly formulated rules of science.” I take a publication that I call scientific and soon find a sentence that no doubt may pass for one, “Behind every radioactive element its half-life is listed, whereby *s* means a second, *m* a minute, *d* a day, and *a* a year.” Here a rule is given for the use of the expressions involved (in this case the Latin letters *s*, *m*, *d*, and *a*). As long as nothing more is said about the utterances that are to be regarded as rules, I conclude that rules that have been explicitly formulated always say something (but perhaps never everything) either about the form of certain expressions or about the transformation rules that apply to them, and that they always have a validity range, though one that mostly is not explained. In the case just mentioned, the tabular use of the expressions *s*, *m*, *d*, and *a* is covered by rules, and the table constitutes their validity range. More briefly, we may say that the validity range of a rule can be determined by specification of two things: (1) a topic for discussion (in this case “tables of decay series of radioactive elements”), and (2) one or more authors who set up the rules and intend to use them.

We shall not delve into the question of possible criteria for what in a given concrete text constituting a scientific treatise is to count as an “ex-

plicitly formulated rule.” I think, however, that it would be highly desirable to make this expression more precise, and to do so by means of examples from historically present texts. For rules do not fall from heaven; they are primarily utterances made by definite persons.

It emerges from Carnap’s writings that by “rule” he—often, at least—also understands “implicit rule.” To the implicit rules belong implicit determinations. An example is “If from the totality of all numbers one separates a finite or infinite part according to some point of view or other, then this part forms a numerical set.” Here something is determined about the expression “numerical set.” From Carnap’s doctrine on pseudo-object sentences, it becomes clear that his concept of an implicit rule is very wide. For the implicit rules as well as the explicit ones, it holds that they occur in certain fields of science as products of the activities of certain authors at certain moments. Moreover, any determination of the implicit rule in a given text is afflicted with the same kind of uncertainty as every other activity. One has to count the possibility that different people can come to different conclusions with respect to the question of which rules are implied in a certain case. This shows the necessity for concrete specifications of how the “rules of science” are arrived at.

In addition to explicit and implicit rules for the formation and transformation of scientific expressions, there are observable regularities among the expressions. Regularities may be taken as symptoms of rules if one assumes that a rule is more or less consistently followed and that thereby a systematic distribution of the expressions often emerges. The trustworthiness of the regularities as symptoms of rules is a matter of observation. There are also regularities that are seldom mentioned in rules. In Carnap’s publications, for example, expressions are usually ordered in parallel layers that run straight across the pages. When one finds that the distribution of certain expressions obeys a certain law G_1 , then it also (for example, according to Newton’s interpolation formula) turns out to obey other laws. One cannot therefore say that the distribution follows a certain rule. One could, however, say that among any number of rules it also obeys a certain rule R_1 . This mode of speech is inadequate inasmuch as it may evoke the understanding that rules as names for regularities of signs are quite something else than regularities in other phenomena (for example, in the distribution of a species of trilobites). In the following, we shall not call statements about regularities rules.

The Expression “All Terms of the Language of Science”

We have now reached a stage at which we can undertake an analysis of the expression “all terms of the language of science” as a whole. As examples of terms, we believe one can list *pitch*, *volume*, *cross section*, *pain*, and *true*. *Terms* and *expressions* belong to the terms as well, insofar as the syntax of the language of science is understood as part of science. “Syntax, pure and descriptive, is nothing more than the mathematics and physics of language” (Carnap 1937: 284). (We here allow ourselves to assume that by “language” Carnap does not mean “system of rules” but “expressions that show regularities.”) What is to be understood by “all terms of the language of science” depends on which concept of “rule” is chosen and on how the relation of terms to language is understood. According to the technical meaning Carnap gives to the word *language*, it would seem that the expressions to which rules refer constitute the “expressions of language.” Then “all terms of the language of science” must, as far as I can see, mean all those terms that are (1) affected or (2) completely regulated (meaning, their usage is completely determined either by the explicit rules for expressions of science or by the explicit and implicit rules for expressions of science).

Apart from these four possibilities, there are at least four others—if regularities in the usage of scientific expressions are taken into consideration. I mention this only to emphasize that if one wants to settle the question of the final meaning of the expression “physicalism,” one has to make a choice. When reading about physicalism I continually have to choose, without knowing which choice the author has made.

The difference between (1) and (2) I understand in this manner: when there is at least one rule that refers to a certain term, then that term is affected by that rule. When one stipulates about use of the expression “ \circ ”: “Division by \circ is not permitted,” then this expression is already affected by this rule. In connection with symbolic languages, one often claims that usage has been completely determined, and not just for the situation in which the term is possibly ambiguous. I see no reason for supposing that the usage of an expression can be completely and univocally regulated.³ To come to an assessment of physicalism, it suffices to assume that one can speak about more or less complete determination, and that a very high degree of completeness is possible. As has often been emphasized, symbolization does not guard against ambiguity of the rules, since these are introduced and com-

mented on by means of nonsymbolic languages. After the rules have been introduced, one can, of course, formalize them using only symbols, but these symbols must be introduced by means of ordinary language. If Carnap's concept of rule is to be directly applicable to a given text—to geological writings, say—one must be informed about how he roughly imagines the determination of the usage of expressions, at least for some concrete examples.[9]

What Are the Terms of Science?

Let us take a scientific text as an example. In Holleman's *Lehrbuch der organischen Chemie* (Textbook of organic chemistry), section 28, we read that "Methane occurs in the gases flowing from volcanoes." It seems rather clear that one can find at least one explicit transformation rule for the expression "methane"; consequently, this is a term of science. "Occur" is hardly affected by the rules of chemistry. It is, however, present in its vocabulary. One can interpret the latter as a system of rules for the use of words; hence we can also say that "occur" belongs with the terms of science (provided implicit rules are counted as belonging to the language of science). In this manner, one can probably leaf through all of Holleman, and it seems to follow that the expressions of complete texts are expressions of science. When I count a text T as belonging to science, then the expressions of T all belong to the expressions of science, provided (1) one understands the concept of rule as so wide that implicit rules are included, and (2) all terms that are affected by rules are counted as belonging to the language. If the vocabularies are to be utilized as sources of rules, then one must realize that hardly a single term of occult writings falls outside the class of scientific terms. Suppose t_1 is a term of the object language and also belongs to the language of science; it cannot be excluded that one can find a term t_2 that the vocabulary connects both with t_1 and with t_3 —an occult concept. Thereby the term t_3 is affected by transformation rules of science and consequently belongs to science—according to Carnap's explanations.

If, on the other hand, one demands that the use of an expression be completely and uniquely determined if this term is to be reckoned as belonging to science, then I believe there are no terms of science. In any case, I know of no example of such terms. It would be a weighty argument if the physicalists could present such a term.

Carnap's Term *Physical Language*

Let us give the name "physical language" to that language which is used in physics. It contains the thing-language, and, in addition, those terms of a scientific methodology which we need for a scientific description of the processes in inorganic matter.

(Carnap 1936a: 467)

Let us give the name "thing-language" to that language which we use in everyday life when speaking about the perceptible things surrounding us. . . . A sentence of the thing-language describes things by stating their observable properties or observable relations subsisting between them.

(Ibid., p. 466)

Let us immediately notice that Carnap's style in his treatment of this question is quite different from the usual style in his *Logical Syntax of Language*. The expression "perceptible things surrounding us" is almost lyrical in its indefiniteness compared with expressions such as "numerical expression," "logical content," and "functor-variable." A linguist or psychologist would not seriously proffer statements to which "rules for expressions we use in everyday life when speaking about the perceptible things surrounding us" would not be applicable. How are we to distinguish such expressions from others? Countless questions arise and demand a solution before one can take the expression seriously. Carnap does not offer any helpful comments—one simply has to accept the expression in order to continue. I take it that the matter is simplified by Carnap's statement that the "thing-language" describes things by means of sentences about observable properties or observable relations between them. In the following, I shall therefore analyze this definition (*Bestimmung*) and disregard other ones. The analysis is rendered more difficult by the fact that "observable" can be interpreted in several ways. Were Carnap of the opinion that a sentence belongs to the thing-language whenever he—or another authority—concludes that it says something about something observable, then other conclusions would follow under other interpretations. In the said case, the question of whether the sentence—as a complex of signs—does or does not contain observation terms would be unimportant. The weight of the sentence would depend on whether experts find that it expresses something observable. Meanwhile, I find no indication in Carnap's texts that would make such an interpretation

probable. The most reasonable interpretation of “thing-language” therefore seems to me to be that it consists of sentences that contain observation terms. This leads to further conclusions.

According to Carnap, the physicalist language is to consist of the thing-language and the technical physical language. This specification indicates that Carnap does not count the terms of the complete text of a physical treatise among the expressions of physical language. It is very easy to see that only a fraction of the expressions are observation terms or technical terms. On the other hand, it seems likely that very many expressions of ordinary language are to be found in physical treatises. This means that texts have to undergo a reduction before one, on Carnap’s definition, can say that they are now written in physical language. We could formulate guesses about how this reduction could be done, and one cannot say that Carnap has not expressed himself about the concrete execution of the reduction. It will suffice to observe that it is a thorny and complicated matter in whose executability I rather believe, although it has not yet been demonstrated. Theses about such reducibility are worthless, but research programs are fruitful.

Carnap’s Term *Reducible*

The main difference between the formulation of physicalism in the period 1932–1935 and the 1936 formulation is that the terms *definability* and *translatability* have been replaced by *reducibility*. It is desirable to arrive at clarity about this difference. It is easy to characterize the distinction in abstract terms: There are cases in which scientists introduce sentences that cannot readily be tested by the production of an experimental situation. Nor can they be eliminated by substitution. One can, however, often indicate the observational conditions under which they are to count as verified, as well as the conditions under which they are to count as not verified. Carnap believes that this manner of introducing sentences, and thereby terms, is legitimate. This implies that the earlier formulations of physicalism must be abolished. They presuppose that terms that have once been introduced can be eliminated, namely by the equivalences that define them. The expositions on reducibility seem to be clear—until one starts to look for examples of sentences that cannot be eliminated on the basis of a definition and that

nevertheless can be verified via reducibility. Carnap's example on page 64 of "Testability and meaning" is extremely complicated and anything but clear to me.[10] I believe, however, that the distinction between definability and reducibility can be clarified. This would presuppose the analysis of many examples, which would require complicated comments and explanations. Without such explanations, the distinction between the sentences that are concretely available in some scientific treatise, with a description of its properties, and a rendering of these sentences in a symbolic language with specified introduction-clauses, is much too large to secure an unequivocal rendering.

I make the following prediction. Given ten people who have made a serious study of Carnap's writings and whose intelligence quotients are not lower than 125, Carnap is allowed to choose ten sentences, by means of a random procedure, that in his opinion partly can be tested directly and partly can be introduced by reduction. The subjects are given the task of indicating the conditions under which the testable sentences are testable, and how the terms of the reducible sentences can be reduced. Here is my prediction: fewer than eight sentences will "correctly" be judged to be testable or reducible. More than 50 percent of the given testing conditions or reductions will differ from those that Carnap had set up. My confidence in the unique feasibility of the reduction of sentences would greatly increase if this prediction, whose further elaboration I leave to the physicalists, is not confirmed.

The reducibility of sentences seems to me to be a formalized expression for the specification of the meaning of a statement by "operations" (Bridgman). In those cases in which this method is successful, reduction will also be successful; when the specification of certain operations is practically excluded, reduction will be dubious as well. I therefore think that reducibility should definitely not be regarded as a necessary condition for the scientific legitimacy of a sentence.

Now suppose that reducibility is instead taken as a sufficient condition. By "reducibility" we shall not understand "general reducibility" but "nongeneral" or, as I shall call it, "singular reducibility." When one investigates metaphysicians' writings, one finds that their sentences and terms are singularly reducible to sentences and terms of physical language.[11] For example, they commonly use historical events as arguments. These are usu-

ally formulated in ordinary language. What most metaphysicians do not want to admit is precisely that their terms and sentences may be translatable, meaning eliminable. Without a systematic investigation of concrete examples of antiempirical formulations, it is not possible to set up decision criteria.

In my opinion, it follows from what has been said that the criterion of reducibility cannot be used as a decision criterion, for two reasons:

1. General reducibility as the criterion excludes most, if not all, present sentences of scientific texts.
2. Singular reducibility as our criterion cannot prevent the inclusion, for example, of occultism and metaphysics of every kind in science.

Concluding Remarks on the Formulation of Physicalism

It is not possible to take a uniform standpoint on physicalism since the concept is not unequivocal. Even if one takes the concept of rule as so wide that implicit rules are included and one understands “reducible” as “singularly reducible,” many scientific statements are excluded from physicalist language by the physicalists’ thesis. On the other hand, some statements that one does not like to see as scientific are thus reducible. In short, there are terms in scientific language that are not reducible to the terms of physical language, and there are nonscientific terms that are reducible to physical language.

If, on the other hand, only explicit rules are included in the language of science, then the physicalist thesis becomes a thesis about infinitesimal parts of the texts of the scientists. If—a third possibility—one starts from “reducibility” in the sense of “complete reducibility,” then I fear that there would not be a single scientific text whose terms are reducible to physicalist language.

Our assumptions concerning what Carnap understands by the words *language*, *scientific*, *rule*, *observable*, *reducible*, and so on, on which we have based our conclusions, are numerous, and hard to check at that. It is therefore more appropriate to say that, given the way in which physicalism is formulated today, I do not have the necessary means for understanding it, not to speak of testing it. One might retort that under these circumstances

it would be better not to mention it at all or else to await the offer of more material from the physicalists. It is questionable, however, whether the physicalists take supplementation to be necessary.

As the physicalist thesis lies before us today, it indicates a special attitude toward certain very general questions. Perhaps we may be allowed to read one of Carnap's remarks at the end of "Testability and meaning" as saying that the thesis is meant as no more than a suggestion: "The object of this essay is not to offer definitive solutions of problems treated. It aims rather to stimulate further investigation by supplying more exact definitions and formulations, and thereby to make it possible for others to state their different views more clearly for the purposes of fruitful discussion" (Carnap 1936a). There can be no doubt that Carnap has reached this goal. He has introduced new and fruitful precisizations (*Präzisierung*) in areas of debate in which precise formulations are extremely rare. However, one cannot achieve a uniform, equable precision at one blow where there was none before. Carnap's manner of making his statements more precise may be called insular insofar as he attempts to set up theses about science in general or about empiricism (for example, responses to positivism).[12] Most of the relevant questions one would have to raise have not yet been formulated empirically, not to mention the task of making them sufficiently precise. This makes it even more desirable to produce recommendations for expository and discussion practice. Such a focus does not block the way for a later use of them as supportive reference material for far-reaching theses.

The methodical avoidance of an exposition in terms of "theses" when "recommendations" would better suit the situation has admittedly not yet become common practice. It becomes a matter of course, however, when a unification of the sciences is achieved in the sense of the empirical movement. Later on, I shall touch upon the questions forced on us by Neurath's idea of the encyclopedia. One should not lose sight of the fact that the physicalist speaks of Science as a whole, and hence makes statements that I as an empiricist want to treat with the greatest caution. For, in general, such statements are nothing more than substitute products—and poor substitute products at that—for metaphysics, unless they are simple defense formulations against metaphysics. This is the way in which I, for example, understand my own treatise *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge Acquisition and Scientific Behavior).

Is It at All Possible to Determine the Meaning of a Statement?

Closely connected with the question of physicalization is the question of whether the physicalists are intervening in the psychologists' discussions and, if so, with what success.[13] Carnap and Hempel have more than once emphasized that such intervention does not and cannot take place. Nevertheless, one finds Carnap writing, in connection with the derivation of protocol sentences from physicalist sentences: "In descriptions of states of the body attention should be given above all to the state of the central nervous system, and here again in the first place to the cerebral cortex." Admittedly, he does add: "For our purposes it will not be necessary to go into further details" (Carnap 1932a: 457). Does the logical aspect stop exactly here?

The quoted utterance by Carnap is "of a logical nature" insofar as one can maintain that the statements of the neurophysiologists are chosen as objects of research, but is the selection of statements by neurophysiologists, who often contradict themselves, made according to logical criteria? There are neurophysiologists who maintain that they use Bergson's philosophy in their own work. I do not know by means of which syntactic rules one could justify choosing the opinions of one physiologist over those of another. In any case, there is a conspicuous similarity between Carnap's logical theses and the theses on the philosophy of nature formulated by materialistically oriented physicians in the nineteenth century. Certainly, this similarity is no argument against Carnap's theses. It remains to be seen, however, whether ideas of this kind will suffice for the solution of the problems that occupy physiological and psychological research today. The scientists themselves do not agree on this point. Among physiologists, there are quite a few who talk about "brain mythology" when ideas of the said kind are brought forward. This assessment is amply represented precisely among behaviorists and scholars of related provenance.

Voices are heard against the wish to reduce behavioral laws to laws formulated by means of the customary, although heavily misused, concepts of physiology. By such a reduction, one often only achieves the replacement of clear and pure and practically testable statements with statements of dubious testability that are no more suitable for use in further prognosis—some would say less.

We shall not take a stand in this discussion.[14] For us the only important question is, Does one always stand up for empiricism by propagating the thesis of physicalization? I believe that it is often worthwhile to emphasize the achievements of the physicalists. In certain discussions with relevance for the general question of empirical decision criteria, it would, however, not be useful. Statements on reducibility ought to be avoided as too speculative. Instead of statements, we would like to see programs, which ought to be differentiated over the various front lines of research.

The examples that have been adduced in favor of physicalization show that the physicalists do take a stand, at least indirectly, in regard to the ongoing discussion in physiology and psychology. Some questions in the physiological discussion admittedly do have a logical aspect, and Carnap has tried to isolate this aspect. Over and above this, however, the physicalists have their own opinions in matters of physiology and psychology. The isolation of questions of syntax from object questions as a program for future discussions cannot be dealt with here.

The syntactical properties of the language of science are changing with time. It is hardly possible to isolate them completely from the other properties of the language. In fact, such an isolation might be a liability to the empirical attitude. At least this may be said when Carnap's theses are interpreted in a certain and very reasonable manner. Given the clearly empiricist basic attitude that Carnap has displayed on other occasions, one might regard this interpretation as unjustified. I find it difficult, however, to give a sense compatible with the empirical attitude to the following utterance made by Carnap:

In applying a procedure we are free [he refers to the experimental method in psychology], but not in our interpretation of the sentences we have obtained. The sense of some sentence, however arrived at, does not issue unequivocally from the logical analysis of the procedure we have used to obtain and to test it.[15]

(Carnap 1932b: 138)

Sense, content, meaning, and similar words seem to be very simple things. From the way they are used, one gets the impression that it would always be easy to find "the sense of a sentence." Assertions about the meaning of a statement, *p*, are best understood as hypotheses, however,

provided the assertion is somehow supposed to be brought into connection with the current use of *p* in linguistic communication. One might expect statements about “obtaining” and “testing” systematic sentences to have the form of protocol sentences, but if we look at historically extant sentences about “obtaining” and “testing,” they are seen to contain very abstract, very compressed, and often rather unclear indications about what is essential in this “obtaining” or “testing.” A description of the type of behavior that goes with the uttering of systematic sentences is clearly out of the question. Nor do we find any indication (1) about how to describe such behavior and (2) by means of which rules one could distill what is needed for the determination of this “meaning” from a report on behavior. (1) presupposes that very complex and quite unresearched questions of behaviorism have been solved. Not even conventions are available that could tell us how to carry out the description. If there were any, then the physicalist would be justified in saying that his theses do not presuppose any solution to behavioristic questions.

From this relationship between statements about the “procedure” for obtaining and testing systematic sentences, and the sentences themselves, it becomes clear that to the statements about “the meaning of a sentence” one can apply the Duhem-Poincaré thesis, according to which a plurality of theories can be coupled with any given set of experiential data.[16] Systematic sentences about “language,” “syntax,” “deducible,” “analytic,” “provable,” “decidable,” “sequence,” “formal determinants,” “true to content,” “*gehaltfremd*,” “physical,” and “meaningless” do not constitute a class of exceptions in the sense of being uniquely decidable.

The difference between a “logical analysis” of a sentence and a behavioristic description of its functioning is not that the results of the former are irrevocable and those of the latter are not. Expressions like “content,” “form,” and so on are admittedly defined in a partly arbitrary manner, but such definitions cannot always be applied to given statements. Whether an expression has been applied as stipulated is not merely a question of stipulation but a matter of observation as well.

The general opinion that “the meaning of a statement, however it is arrived at” is “uniquely determined by a logical analysis of the procedure by which the statement was obtained and tested” seems to me to be incompatible with the Duhem-Poincaré thesis. Precisely this thesis seems to be a

good instrument against absolutism (Neurath's "pseudo-rationalism"), and as such I regard it as indispensable for empiricism.

Specification of Space and Time Coordinates Does Not Protect Us from Antiempiricism

The relationship between everyday testing methods and physicalism cannot be analyzed further unless one is prepared to delve into physicalistic conceptions of space and time. Neurath has suggested some formulations that are to allow for the difficult transitions between expressions of "trivial language" and those of an "advanced physical language" as well as to guarantee that metaphysical language is no longer possible. A crucial role is assigned to the criterion of whether a statement contains specifications of place and time. "Within the framework of unified science there are only statements that are reducible to spatio-temporal terms" (Neurath 1936c, 281). "Thus every science is similarly reduced to spatio-temporal terms, which constitute a complete basis for the construction of the protocol sentences" (ibid., p. 282). The presence of specifications of space and time is used as a criterion for the meaningfulness of a statement and thereby also as an empirical decision criterion: "One starts from observation sentences that in advance already contain measures of space and time, albeit in an imperfect manner. There will always be formulations concerning space and time beyond which one cannot go without saying something that has no meaning" (ibid., p. 298).

Let us try to find out what is meant by the expressions "space," "time," "to reduce to spatio-temporal terms," "to contain measures of time and space in advance," and to what extent specifications of space and time are a protection against metaphysics.

Everyday observation utterances do not have to contain specifications of time and space. If one supplies them with additional specifications of time and space, one does so on the basis of hypotheses. An a priori judgment to the effect that observation statements could always be integrated into the "spatio-temporal" sentential system would, however, have a taint of critical neorealism. One would thereby also have to distinguish between physical, physiological, and psychological (so-called tactilo-motor) spaces

of various kinds. Only by very tedious experiments is it possible to obtain practically testable statements about the nature of the “spaces” and “times” into which the sentences of everyday life are incorporated. The philosophical concepts of (the one and only) Space and Time (“as such”) are as inapplicable as physical spaces (for example, as classified according to some “operational” analysis à la Bridgman).

Since I assume that Neurath was aware of this, I presuppose that by “spatial and temporal specifications” he did not mean specifications concerning a certain spatio-temporal incorporation but either (1) specifications for the incorporation in some space and some time, or (2) specifications for the incorporation of statements about events into “history,” as history is understood in ordinary life. If (1) is meant, then Neurath’s definition of physicalism is too indefinite to make it possible to take a position on it, and if (2) is meant, it seems to me that specifications of space and time do not suffice to eliminate metaphysics. Many metaphysical formulations are full of specifications of space and time.

For example, the metaphysical writings of Rudolf Steiner contain a profusion of specifications of space and time and of observational terms of all kinds. The presence of these terms avails little. The metaphysical writings of Descartes, too, according to the usual interpretation given to them, contain statements that suggest how they can be reduced to statements about spatio-temporal events. The presence of general rules for this reduction may now and then be taken as an indication of a basically metaphysical attitude.

The requirement of reducibility to spatio-temporal terms is therefore of no importance for a strict empiricism; it is actually even incompatible with it. For the rest, I cannot see how one could test in practice whether the requirement can be satisfied and whether it is satisfied. That holds of every interpretation of the concept ‘to reduce’ which could be of relevance in this connection. Let us assume that Neurath would furnish rules for carrying out the test. Even so, one could not predict whether the statements that often come up for critical reviewing could be divided by Neurath’s demarcation criterion into two classes, one of which would contain those statements that at the moment are regarded as tolerably certain statements of natural science whereas the other would contain those statements that are usually deemed metaphysical.

Research Programs Instead of Theses: Models Instead of Systems

The great scientific successes of physics and its magnificent rise give it a special position from the point of view of the sociology of science. I say "sociology" because a serious history of physics needs to be undertaken from a sociological point of view. The material for such studies would be the utterances of a certain group of scientists, their instruments, the behavior of group members among themselves (collaboration, confidence, etc.), as well as their influence on the development of techniques, their position as scientists at universities, and so forth. The question of which factors have been the strongest in bringing about the current state of physics is an extremely involved one, at least if one wants something more than a list of names of these factors ("experimental method," "rejection of scholasticism," etc.) and wishes to find out which specific features of physics can be seen as symptoms of the influence of which specific factors.

The great diffusion of metaphysical materialism and its tendency to "reduce" all events to "material" or "energetic" processes exemplify the enormous effects of the successes of physics. They have no value for an empirical logic of science and theory of science. As we have already said, physicalism has quite different goals. In the first place, it is supposed to indicate the direction in which serious scientific activity moves in the nonphysical sciences, and in the second, the consolidation of all science is supposed to be made possible on the basis of the working methods in physics. The goals one sets oneself are often indecisive, and I believe that the physicalists' endeavors may be characterized by saying that they tried to catch the spirit of physical research, which they saw as particularly exemplary for "decent" (Neurath) scientific activity, in *one* formulation.

The first formulations were, however, conceived in too close dependence on a specifically physical conceptual mode. Too much was demanded of the nonphysical sciences in the direction of adjustment to physics. Today the formulations are much weaker. True, they are still of the same enormous generality—they all pertain to "all terms of the language of science"—but they nevertheless make demands only on the expressions (numerals and sign sequences) of the sciences. Nothing is said about the meanings of these signs and sign sequences. Nothing is being said about

the relation of physical sentences to the behavior of the scientists, nothing on the virtues of the style of physical treatises as a means of communication in a group of scientists. The reformulated physicalism therefore only very imperfectly realizes the original aspirations. At the same time, the physicalistic formulations have become dependent on the acceptance of highly complicated conceptions of a logical nature, namely the Carnapian doctrine of the syntax of the language of science, which today admittedly is the apogee of precision and clarity but which still is in the middle of its development. This already makes it impossible to gather empirically oriented scientists around physicalism. Acceptance of physicalism would contradict the commandment of carefulness towards general theses. On the other hand, the wide generality of a thesis has the effect that it becomes very hard to justify it and that one's efforts to do that are not related to the more specialized discussions about physically tinged questions that are carried out today in the nonphysical sciences. Such discussions are particularly frequented in the fields of biology and psychology. Programs and suggestions for research in limited areas would be natural here, rather than theses of the most general kind.

When psychologists have nothing more serious to do, they construct "systems"; they "define" psychology, isolate themselves from one another (autarchy of schools), and give outsiders the impression that scientific progress depends on finding the best psychological system. There are more than half a dozen in the behavioristic style, and several in the vein of Gestalt psychology, psychoanalysis, and philosophy of mind—to mention only the ones that are most vocally expressed. The efforts to unify psychology and all other sciences are given an unfruitful direction when one tries to find watered-down formulations that will satisfy all systems, on the basis of an analysis of the so-called fundamental concepts of the various systems. For the "fundamental concepts" are, of course, only the banners under which one school combats another school.

In fundamental opposition to this attempt is the effort to find the common focus of the various "psychologies" by unburdening the conceptual superstructure. Thereby the center of gravity is posited not in the general theses of the various schools but in their actual working methods. True, this will reduce the possibility of arriving at elegant formulations about the concepts they might have in common, for one will now have to pay at-

tention to completed singular experiments and to particular (not unnaturally generalized) results.[17]

Here I have come to an essential point concerning the evaluation of the physicalist thesis. Since the goal is a general thesis and not, say, a definite, well-delineated program, one thereby supports the above-mentioned thesis that the unity of science is to be sought in theoretical structure, namely, in auxiliary concepts and general models. In the field of psychology, physicalism one-sidedly supports the conceptual superstructure of molecular behaviorism.⁴ However highly one esteems molecular behaviorism—for example, in the form given to it by Hull⁵—by such an overt choice of sides concerning the systems of psychology no common platform for psychologists can be found.[18] One demands too much from the psychologists; one demands their acknowledgment of diffuse theses that at the most can be tolerated as research programs but that have been formulated far too absolutistically. I personally think that it is compatible with the empirical attitude to devote all one's energy to a certain research program, that is, in a certain direction. Absolutism in the choice of problems is caused by the fact that there are limits to what an individual can accomplish in science. This does not necessitate a categorical formulation of the results one hopes the program will yield. Absolutism of action in no way implies an absolutism of hypotheses.[19]

Psychologists are forced to choose a direction in their practical work. They are inclined to defend this direction against other claims by means of system-building. In my opinion, this can be explained by the following factors in the sociology of science: The number of psychologists is very small in comparison with the complexes of questions that are to be comprehended by a scientific psychology. The lack of tradition makes the position of psychologists less secure than, say, that of physicists or students of medicine. Enormous numbers of fragments of science of all kinds have been known in wide circles for a long time, but only in a completely unorganized manner in the form of "agglomerations" (Neurath: *Ballungen*) of statements that are positively crying for systematization.

In this situation and in the interest of the unity of science, it is above all necessary to fight against exaggerated systematic claims of all kinds. The inclination to present special methods of thought as absolute hampers the universal expansion of the specific sciences and thereby hampers a real unification as well.

On the Reification of Theoretical Constructs in Psychology

Philipp Frank (1917) has said that the lasting nucleus in Mach's doctrines was his feud against "the reification [*Vergötzung*, idolization] of theoretical constructions."⁶ The physicalists may be said to have carried on this feud with considerable success—insofar as they did not apply the thesis of physicalism. If the expression "theoretical concept" (*Hilfsbegriff*, auxiliary concept) is understood so widely as to include the atomic models, then I suggest speaking of "models of thought." Among models, some are always regarded as particularly fundamental. There are still textbooks and popular writings in which the impression is given that the achievement of physics is to have discovered that there *are* atoms. According to this view, physics would be annulled by the elimination of the idea of atoms. Yet these ideas are, in the physicalists' own opinion, at best instruments that allow us to find convenient formulations for sets of observation sentences.

There are models of a corresponding nature in psychology: for example, in psychoanalysis we have the concepts of the libido and the superego; these one can quietly eliminate without decreasing our knowledge. However, difficulties of formulation will result, for these auxiliary concepts have enabled Freud expediently to schematize and abbreviate observation statements. The model of "behavior" as it occurs, for example, in the publications of the molecular behaviorists, differs considerably from that of the superego. It can, however, just as easily—perhaps even more easily—be eliminated from behavioristic treatises without any loss of psychological knowledge. In consequence, the controversies between behaviorists and representatives of other schools often lose their meaning. What has been said about "behavior" holds as well, I believe, for expressions like "gestalt" in Gestalt psychology and "object" in Brunswick's psychology. The same also holds, however, for terms like *synoptic resistance* and *nerves*, used by the protagonists of the closest possible connection of psychology to physiology. One thinks that psychology is thereby already scientifically "saved." This is an encouragement for the influential brain-and-nerve mythology, whose adherents have propagated the unity of science for a long time already—in a particularly antiempirical manner.⁷ Those who are outsiders to empiricism—or who maintain that they are—often are of the opinion that the expansion of the habit of raising scientific questions is synonymous with

defending arrogant doctrines that arise from an intemperate generalization of already existing statements taken from the separate sciences, or by reification and generalization—*Vergötzung*—of the auxiliary concepts of the sciences. Diametrically opposed to this diffusion is the expansion that proceeds by in-depth analysis.

It ought to be mentioned that science cannibalism and science unification are different things. Precisely in our time psychologists, biologists, and sociologists are beginning to offer their own science as “universal,” in all possible and impossible senses. Biologists wish to see physical laws as special cases of biological laws; universal psychologism breeds new trends that are dangerous precisely because they take as their point of departure the doctrines of very successful scientific disciplines. Thus, for example, the author of *Erkenntnis und wissenschaftliches Verhalten* seems to want to see everything as questions of “ordinary observable behavior.” Tendencies toward science cannibalism are more pronounced than ever. Earlier, only physicists had much success as cannibals. Unity of science is rooted only when theoretical cross-connections (Neurath: *Querverbindungen*) entail consequences that allow for more effective prediction. The requirement can perhaps be given a less dogmatic formulation than has been done above, more in the form of a program.

Those attempts to arrive at an apparent unity of science by an enormous generalization of the field of application of certain models or theoretical concepts must be combated with the same determination as the view that the state of the sciences today makes for a chaotic spectacle. The latter opinion rests on, among other things, an overestimation and misjudgment of the role of the so-called fundamental theoretical concepts. From the fact that scientists disagree about the scope of various “fundamental concepts,” one concludes that the house of science stands on wobbly legs; because there are ten “psychologies” there is none at all.

Physicalism and Some Proposals Concerning the Technique of Discussing

I do not know to what extent Neurath and Carnap today (1938) still accept the statements of their own writings on psychology and the “language of psychology”; their publications on the subject date from the earlier phases of physicalism. For this reason I shall leave the matter here.

There are many remarks in Carnap's and Neurath's writings that lead me to assume that physicalism and the empirical decision criteria are to be understood as technical recommendations for how to proceed in a discussion. In any case, those authors will probably be prepared to let the "theses" be registered also as technical instruments for use in debate. Neurath's dictum "Physicalism is the manner in which one works for the unity of sciences today" could be used in support of this assumption. I could accept this dictum provided it were reformulated as "The reduction of terms that lay claim to a scientific status to terms that belong either to the stock of words in ordinary language or to the technical terms of physics, is one method that can be used to promote the unity of science today." (Corresponding utterances on sentences and laws might be added.) Personally, I would like to add one or two other statements of this kind, such as: the unity of science can be promoted by a reduction of sentences laying claim to a psychological or philosophical status to sentences about experimental observation conditions. This does not imply that the reduction is to be carried out once and for all, or that it must be conclusive and exhaustive; that would also contradict Neurath's recurrent emphasis on the dependence of theses—for example, physicalism—on time. The claim to finality and completion is an abortive attempt to beat the metaphysicians on their own grounds. One fears that a refutation that does not expressly condemn non-empirical formulations to eternal and unconditional separation from the field of science will be considered feeble and impotent. Someone who reacts this way is not very likely to be influenced by absolutistic versions of empirist statements either.[20]

An antimetaphysical attitude does not always protect against metaphysics, provided something more is meant by that expression than Heidegger's rhetorical style. In the interests of a radical empiricism, one ought to encourage an ametaphysical attitude, of which the antimetaphysical attitude can be no more than a preparatory stage. The opposition between "metaphysical" and "empirical," as it appears, for example, in the Vienna Circle, has been determined and clarified in the course of discussions. I believe that the views of the empiricists who have taken part in these discussions differ from those of their adversaries in this essential respect: when points of view are at war with one another, the empiricists try to find a suitable point of departure for further discussion by means of trivial, everyday

concepts and models of thought taken from ordinary language, whereas the metaphysicians remain stuck in the nontrivial, in the depths of thought, and not merely in “speculation” but in the “unconditional” as well. Above, I have discussed one type of philosophy of the unconditional: that of “the logical” as “the formal,” “that which comes before all substantial (scientifically professional) reflection.” When the discussion concerns, for example, the necessary conditions for scientific linguistic communication, or protocol sentences of the strictest kind, then it would seem that serious differences of opinion could be overcome by taking a step backward—that is to say: not in the direction of a beyond-the-ultimate, of a “meta-beyond,” but in the direction of the trivial. I have the feeling that the differences between the antimetaphysical and the ametaphysical attitudes are in part of this kind. Insofar as my own standpoint does not coincide with the standpoint of the physicalists as represented here, I would therefore choose to call it trivialism.[21]

The Encyclopedia Project—Its Significance for the Empirical Movement

The indications given by Carnap and Neurath that physicalism and the empirical criterion are not to be understood as doctrines but as general recommendations about techniques of discussion and methods, are underscored by their pronouncements on the encyclopedia project.⁸ The project of an encyclopedia based on Neurath’s principles seems to be the logical development of the ametaphysical empirical movement. One promotes the positive elements in empiricism precisely by organizing the efforts of those who want to work in the service of the empirical movement and through attempts to build a common language; empiricism in the sense of doctrines with a philosophical tinge is forced back.

The distinction made between “system” and “model” in Neurath’s publications about the envisaged encyclopedia signals a renunciation of attempts to meet antiempirical movements on their own grounds and with their own weapons. “System” is rejected and “model” placed in the foreground. It is hopeless to try to get empirical research workers to cooperate on a system, but it is not hopeless to call on them to cooperate toward a limited, qualified, and elastic unification.

For an encyclopedia as envisaged by Neurath, the distinction between decision criteria as doctrines and decision criteria as recommendations for a technique of discussion and exposition acquires the following meaning: decision criteria in the latter sense prevent the occurrence of a third world of statements in addition to the scientific statements of the encyclopedia and the representational rules of the encyclopedia (that is, the rules for the scientific statements in it). In other words, one prevents theoretical or “auxiliary concepts” (in Frank’s sense) of the encyclopedic exposition from being taken as absolutes and ending up as the superstructure of theses about the encyclopedia itself.[22]

The difference between decision criteria that have an unlimited range and those whose application is limited to certain discussions is essential to the encyclopedia. The connection between actual concrete problems of exposition in certain fields—for example, that of “the compatibility of behaviorist and psychoanalytical sentences”—now becomes conspicuous. The recommendations concerning discussion and exposition will become more pliable when the final court of appeal for their formulation and validity range is constituted by the particular problems of the field in question. When they immediately are elevated to the status of rules with universal validity, it becomes more difficult to change them according to the situation in a given area of debate: they take on a value of their own, and an “idolization of auxiliary concepts” (Frank) is hard to avoid.

Rules for discussion and exposition are often postulated indiscriminately for large areas of discussion and with no clear explanation of the purposes to which they owe their existence. The so-called psychology in physicalism has convinced me that such rules lead to violation and oversimplification of the factual situation in those areas. The problems of psychology and the many valuable attempts to find compatible solutions for them are so complicated that any reduction of their terms must take place from the inside, with attention given to each discipline and to each attempt.

More than once I have characterized Neurath’s idea of an encyclopedia as a further development of the empirical movement. The discussions about physicalism and protocol sentences may have appealed to philosophers, but the encyclopedia project appeals to a wide circle of empiricists who personally are disinclined to take a position on theses of the most general kind, such as those on physicalism or decision criteria. As Carnap and

Neurath have emphasized, it is very possible to work on the encyclopedia without assuming such theses. What is revolutionary about the encyclopedia project is—partly at least—that one aspires to and also assumes the possibility of a more intimate and many-sided cooperation than has been realized in any collective scientific labor hitherto.

There is one exception to this: work that has been achieved by men subscribing to the same ideology. The encyclopedia of the so-called Encyclopedists of the eighteenth century was primarily the work of an ideologically homogeneous group. The plurality of problem types in present-day science already makes it improbable that a reliable encyclopedia could come into being if the task were left to such a group—even advanced methods of collaboration would not suffice. Neither a unification based on a common ideology nor one based on an “upward identification” (as, for example, in the institution of a strong *fürher*) would do it.

In the opinion of the new encyclopedists, the required cooperation can, however, be achieved as a natural evolution of tendencies already discernible within the special sciences. The scientific behavior that is displayed in the investigation of objects belonging to more than one science shows that the special sciences are more strongly related than the conceptual apparatus they have in common might make one think. When a biologist, a physicist, or a worker in the Zeiss lens factories tests an observation statement by means of a microscope, then already the manner in which he positions the instrument on his desk shows that he has some knowledge of a psychological kind—about the distribution of light and shadow, psychologically adequate working methods, and so on. The results he obtains in testing a nonpsychological statement will depend on whether his positioning of the microscope on the desk was compatible with psychological-physiological knowledge.

Opinions may differ as to why the conceptual apparatuses of the various sciences offer so little information about this kind of unity. It is so little known that one is still inclined to assume, for example, that a physicist regards objects merely as heaps of electrons and protons, and that a psychologist sees them only under the aspect of stimulation of the sense organs. The conceptual apparatus of a science is, in fact, treated as foreign to ordinary language as well as to nonverbal behavior (for example, the manipulation of instruments). History teaches us that such a separation of science from

everyday thought and language will in general be exploited ideologically in directions that run counter to the empirical attitude. As Carnap has emphasized, the significance for the encyclopedia of a logical investigation of the sciences is precisely that, through formalization and unification of the linguistic instruments, terms can be introduced in such a way that this separation becomes absurd.

The unification of the sciences may seem to be a relatively clear-cut task, provided one does not try to tackle the problems of border areas and interconnections (as, say, those between biology and physics). However, a task of this kind is closely related to that of promoting the empirical movement. The difficulties are so great that attempts to bridge them end up by compromising with empiricism. At this delicate point the “systems” are brought into action, so that one feigns a unification of the sciences or else subsumes all of them under an external authority such as philosophy or religion.[23] One finds a higher “identity” that creates “order.” As long as the border areas of the sciences are not cultivated with the utmost care, they are dominated by the “autistic mode of thought” (Bleuler 1921)⁹; in between the various specialties, idyllic sanctuaries remain where the tired scientist can nurse his private garden of articles of faith, well protected against the exacting norms he assumes for work in his own special field. Such sanctuaries are, for example, provided today by the “philosophical consequences” that are being drawn from the uncertainty relation, but other problems also offer the opportunity for particularly lovely weekend trips.

The borderline fields are so large that the few who cultivate them cannot be expected to be as reliable and as free from airy speculation as persons working elsewhere. The heaviest battles between empirical and antiempirical tendencies are fought precisely in these fields. Because the questions at stake are so hard to survey, no weapon will promote empiricism in each and every case. Decision criteria and theses like those of physicalism presuppose that the Good and the Bad are as distinct as fairy tales would make them. The existence of a formulation that will unite the empiricists of one area of debate does not guarantee that the same formulation will not encourage pure speculation if applied to other fields. Although there can be no amulet that will protect against antiempirical tendencies, an encyclopedia seems to me the best guarantee for an adequate expression of the empir-

ical attitude. Neurath's encyclopedia as planned is intended to stress borderline questions and questions of cross-connections between the sciences, which greatly enhances its importance for the empirical movement. It would be a mistake to hope for solutions—or suggestions for solutions—to border-area problems. The position of empiricism can be strengthened without such solutions; for empiricism is strengthened already by the evidence we have that one can get by in a border area with those modes of inquiry that have proved scientifically valuable in other fields. The proviso that future work would probably lead to modifications of the formulations of the problems also strengthens it—albeit not in the eyes of those who already are in the possession of “solutions.”

The exponents of the various psychological schools are driven by competition in the market: they vie independently of one another to construct elegant solutions to all the “profound” problems so as to demonstrate the unlimited reach of their own habitual ways of construing scientific questions and the unimportance of all others. It is hard to suppress the belief that even a loose cooperation would bring about a considerable unification of the way of defining the problems in psychology. A first step in that direction will be taken as soon as claims to universality and autarchic demonstrations in the form of theses or so-called solutions are abolished in favor of research programs. Psychoanalysis, Gestalt psychology, individual psychology, *Sexualökonomie*, and behaviorism, to mention only a few, all boast of formulations that are supposed to prove the autarchy of their particular phrasing of problems.

The disappearance of universal solutions would further the empirical movement in two ways: in the first place, by eliminating pseudoknowledge and concentrating attention on practically solvable questions through cross-connections between the schools, and in the second, by completely changing psychology's appearance in the eyes of those who are not professional psychologists. For nonprofessionals, it is hard to distinguish the serious activities of psychologists from the more cheerful ones. When, for instance, one takes the center of gravity of Freud's contributions to lie in his postwar publications and that of behaviorism to reside in its “counterformulations” (*Abwehrformulierungen*) against misuse of introspection, psychology dissolves into a chaos of general and mutually contradictory doctrines. Since these doctrines have a degree of generality that

hardly is inferior to that of the doctrines of speculative philosophy, and since the critical spectator can discern no differences pertaining to the reference material, the impression is created that the situation in psychology is very much worse than it in fact is. That makes it even more tempting to give oneself over to speculation and to pay but little attention to the teachings of professional psychologists. So, whoever wants to promote empiricism clearly takes on a serious task. He must, however, choose a line of attack that is genuinely more practical than those chosen by earlier, philosophically minded positivists and empiricists. He will often have to renounce the theoretical superstructure of his activity or else change it from the bottom up.[24] From the task of unifying science by promoting work on the border questions and clarifying cross-connections, yet another type of task comes to the fore: that of furthering the expansion of scientific modes of inquiry. This is not really a distinct kind of task but rather is contained in the ones just mentioned. Already, in the attempt to unify the language of science—more or less in the way Carnap sees this task—we can see the appearance of problems that have not yet been formulated very clearly and that deserve just as careful a treatment as any problem in wave mechanics.

Summary

Empiricism can be promoted today by unburdening it theoretically. This means:

1. Promotion of teamwork in fields in which there is no tradition of that kind. The main goal is to attain a homogeneous degree of reliability (and precision) of formulations in the total area covered by the team. The intellectual standards that an individual assumes within his own specialty should be extended to the cross-connections with other specialities.
2. A broad and reliable treatment of problems arising from attempts to unify large areas through teamwork. Cultivation of conceptual analysis and of the history and sociology of science. Formulation of recommendations for the unification of modes of discussion and exposition.
3. Formulation of recommendations for sharpening the linguistic instruments of certain groups. Analysis of the consequences of adopting a given linguistic model. A study of the syntactical problems of science.

4. Fight against autistic thought. Furthering of the investigation of scientific behavior as one type of “complex behavior.”
5. Active opposition to the inclination to impede the expansion of scientific inquiry by relying on insufficiently justified systems. Opposition to all utterances that implicitly or explicitly take some formulation of empiricism as final or closed. This recommendation is a consequence of my feeling that the more adamant aspect of empiricism is a general attitude, rather than linguistic observance.

Appendix I: Added in 1956: Notes and Comments on the Paper Written Between 1937 and 1939

[1] Here so-called definitions of empiricism are implicitly criticized. These definitions have a solid basis in the philosophical terminological tradition. I endeavored to change the terminology in such a manner that so-called empirist philosophers could still be called by that name, whereas the usual definitions would eliminate them. This goes for the normative as well as the descriptive definitions. In this connection I assumed that I had found the most important and most valuable elements of empirist philosophy and that precisely these elements went unmentioned in the usual definitions of empiricism. This was, of course, a rather daring assumption.

[2] In the text “empiricists” and “antiempiricists” are spoken of as if a good normative definition of empiricism were already at hand. Since I did not accept the current definitions, the reader may well ask in which sense I used this expression. This is unfortunately not made clear in the treatise. I believe I would be prepared to endorse the following.

Locke, Berkeley, Hume, and Mach, among others, may be characterized as representatives of empiricist philosophy. The most important and most valuable contribution of these and other empirical philosophers does not consist in their explicitly formulated theses, and most definitely not in those formulations by which their doctrines are rendered in philosophical lexicons and textbooks. Rather, it consists in their efforts for the empirical movement, deriving from the empirical attitude.

By “empirical movement” I mean here an expansion of scientific research whereby new fields are constantly made objects of research. Research has a scientific character whenever a continuous intersubjective revision is

made possible and carried out and when one systematically seeks to test prejudices; furthermore, when knowledge of the object is ascribed an intrinsic value. Thereby an indication has been given as to what is meant by “empirical movement” and “scientific character.” The empirical attitude from which the empirical movement springs forth will not be further defined. Nor will it be said what is meant by “metaphysics.” As a first attempt at a definition the following might be useful: a nontestable philosophical standpoint that is defended by an appeal to intuition or to a priori points of view.

In statements in which the term *metaphysical* is used dyslogistically—and this is almost everywhere the case—its replacement by *antiempirical* will not cause serious difficulties. “The metaphysical movement”—an expression admittedly not in use—could be used as a designation for the always recurring tendency to object to scientific research with an “Up to here, and no further!” Thereby one attempts to demarcate problem areas where Hume’s “disinterested attitude” presumably cannot gain ground, or to contest the continuity between all areas of research, appealing to an allegedly separate philosophical sphere of knowledge.¹⁰

It does not seem advisable to use the terms *metaphysics* and *metaphysical* in this sense. On the other hand, it does seem to me desirable to introduce the term *antiempirical* to standpoints that encumber the empirical movement or threaten to thwart it.

In this treatise, I have tried to explain that one cannot set up any useful criteria for a statement’s being or not being compatible with the empirical attitude; furthermore, that it is possible to carry out a philosophical discussion in such a way that it becomes easier to discover and correct antiempirical theses and tendencies, if any.

Against my attempt to reinterpret some of Neurath’s, Carnap’s, and Hempel’s theses as rules of thumb for scientific discussions, one might object that these theses were not meant as mere rules for debate but as philosophical statements. This objection, however, is justified only when one employs the terms *discussion* and *debate* in another sense than that in which I use them. To characterize what I mean, the word *dialectic* might be preferable, whereby one will have to distinguish between eristics (rhetoric) and dialectics, between sophistics and philosophical investigation, roughly in the way that Aristotle and Plato did. In my terminology the debate or di-

alectic constitutes a part of the scientific process, namely, a systematic intersubjective verbal communication whereby misunderstandings are eliminated and the various standpoints undergo the necessary precization¹¹ (*Präzisierung*), so that recommendations for research programs may be subjected to testing. This is not meant as a normative definition but rather as an approximation of a real definition. A normative definition I would formulate in such a way that rules for thematic (objective, to-the-point, *sachliche*) discussion would occur as the definiens.

Understood in this way, the philosophical dialectic (*dialektiké*) seems to me to be today a new edition, of immediate interest, of the classical dialogue (*dialogon*), insofar as this was not merely a literary form but a method for the joint labor of several philosophers. Rules for this kind of dialectical discussion are of high scientific and philosophical import. That is to say, when one reinterprets certain theses as recommendations for such rules, no devaluation of these theses is involved.

[3] In 1938 I was hardly justified in assuming that the direction of this treatise corresponded to that of Carnap, Frank, or Neurath. When I, nevertheless, voiced this assumption, it was more as a hope or a wish than as a well-founded conviction. The conclusions of the treatise contradict, for example, the plan of the *Encyclopedia of Unified Science*.

[4] The reference to *future* research is of the essence. As a social reformer, Neurath was interested in making use of the scientific achievements that were already on record. What mattered to me was, above all, to emphasize our ignorance and to motivate the efforts of the empirical movement in that way. This was the main reason for my definite rejection of attempts to construct an empirist philosophical platform in the form of general theses.

[5] The following are examples of demarcation criteria that do not satisfy the conditions formulated in thesis 1.

1. Incompatible with the empirical attitude are those and only those standpoints that presuppose other sources of knowledge than experience.
2. Only those standpoints that can be corroborated by means of sensory experience are compatible with the empirical attitude.

3. Only those standpoints that presuppose the existence of a priori synthetic statements are incompatible with the empirical attitude.
4. It is incompatible with the empirical attitude to accept unverifiable statements.

If these or similar theses were tenable, I would not regard the empirical attitude as something valuable but as something harmful. If everyone who rejects the “empirical attitude” as characterized in these theses is to be considered a metaphysician, then I must be reckoned with the metaphysicians.

[6] By “empirical movement,” I understand an expansion of the empirical attitude, so that it can continually take effect in new fields, and with increasing consistency and clarity. Such an expansion has been occurring, in fact, since the time of Ionian philosophy, although in certain periods one has to register setbacks. In my small publication *Tenkningens utvikling* (The development of thinking) I made this point of view the cornerstone, although it could hardly be applied to recent years. An introduction to the history of philosophy according to this point of view would require serious changes in the usual arrangement of the material. Only a professional historian would be able to carry out such an undertaking in a satisfactory manner. An improved version of “The development of thinking”—under the title “The development of research,” perhaps—might on the other hand be a stimulant, especially for foundations research in the separate sciences and for the investigation of the relation between philosophy and the separate sciences. (Of course, such an exposition ought not to be obligatory for all students.)

[7] In the circle around Moritz Schlick (after 1938) and in seminars led by him and Friedrich Waismann (now at Oxford), psychologists were sometimes present. The participants were occupied with the “clarification” of psychological sentences, seeking to find and formulate their “meaning.” It thereby turned out that this “meaning” often differed from what the psychologists thought it was, and in many cases no meaning was found at all. These sentences were deemed “meaningless,” although those who used them had for years been of the opinion that they had uttered meaningful locutions. These discoveries were brought about thanks to the criterion of meaning used in logical positivism when the latter was still identical with the Vienna Circle.

My sympathy was with the psychologists, especially when the “clarification” culminated in a decision about which problems within certain sub-disciplines of psychology were to be regarded as pseudo-problems and which were not. It was not easy for the psychologists to refute these charges, which they often felt were unjust. Meanwhile, they used a form of indirect defense that seemed to me effective: they challenged the philosophers to familiarize themselves more closely with psychology and to get to know the research situation that they, the psychologists, tried to master in their investigations and expositions. They held that the clarification then would lead to other and more fruitful results. The philosophical insight of the psychologists was, however, not sufficient to enable them to influence the work in the seminars to any noticeable extent.

In this treatise, I tried to take the psychologists’ demands and similar demands from other research workers into account without throwing overboard what is valuable in these clarification endeavors. In the case of the psychologists, the clarification process could be approximately as follows: When a participant makes a statement *A*, whereas someone else states non-*A*, and it is unclear in what the difference consists, then both participants are to indicate the conditions—which must be possible to realize in a research process—under which they would regard *A* as verified (or corroborated) and responses falsified (weakened). If both were of the opinion that there are no such conditions, then this would count as an indication that neither a continuation of the discussion nor additional research would contribute to the elimination of the verbal difference of opinion between them. At the same time, it would count as an indication that their verbal disagreement is not connected with any more-than-verbal (*sachliche*) difference of opinion.

The spokesman for a philosophical clarification would, then, act as a broker and middleman, not as a judge. He would recommend lines for an effective discussion, lines that would have to differ according to conditions. Instead of pragmatic, logical empirist, and operationalist meaning criteria, series of discussion modes for various situations would emerge. A spokesman for philosophical clarification can very well hold opinions as to the question of cognitive meaning, or about the question of the relationship between cognitive meaning and testability. He should not, however, bring his own opinions about these uncommonly abstract and difficult questions into a clarification task of the said type. Such a task can be carried out with

more success on the basis of simpler and more easily tested premises. The aim is to unburden the task philosophically and to tone down the pretensions connected with it. If that does not happen, then one clearly disguises the fact that more or less expedient rules for discussion and exposition are quite something else than general for cognitive meaning. Research is applied only where one sees gaps in our knowledge.

[8] I have held physicalism in esteem as an important and valuable trend because in spite of its deficiencies it gave expression to the wish to transfer the humble respect of the student of nature for the object of his research, and his readiness to study this object for its own sake, to other fields of learning. In philosophy, the manner in which one approaches one's field of research very often appeared to me to be emotional and sometimes even plainly hysterical, and furthermore ideologically suggestive and not seriously meant. This holds in particular for discussions about the concept of truth.

The uncommonly abstract and general theses of philosophy seemed to me to indicate a deficiency of interest in one's object of research. One has not seriously thought about the possibility of exceptions or about conditions for testing one's statements, nor about the exigencies of an impartial discussion. In this respect, too, the discussion about the concept of truth appeared to me to be the prototype of philosophical working habits.

[9] The logical empiricists showed great enthusiasm for research and great disgust for the lack of clarity demonstrated by the philosophical schools. When they nevertheless could believe in physicalism and in meaning criteria in the form of theses, then this seemed to me to issue from an uncritical attitude with respect to a certain field, namely, that of language. The logical empiricists intended to stick to the logical aspect of language. When one looks more closely, however, it turns out that they made assumptions about uses of language and not about meaning. Here empirical (not logical) research would have been appropriate. I believed that one could purge logical empiricism of antiempirical tendencies by a program for purely empirical studies of linguistic usage. Precisely such research, without further intentions, seemed to me necessary (1) to counterbalance a form of "logical analysis" that strictly speaking was not logical, and (2) to create the preconditions for the construction of a system of exact concepts intended to cover all empirical fields of importance in the philosophical discussion.

This program was frequently met with distrust or rejected as "psychol-

ogism.” This seemed to me to confirm that an essential weakness of the empirist philosophy of that period consisted in its neglecting to promote empirical research in the area of semantics.

Through later contributions, mainly by Charles W. Morris, empirical-semantic problems began to play a greater role in logical empiricism. However, interest in these new areas of research went only as far as covering them under an inspiring terminology. The classifications and statements in Morris’s *Signs, Language and Behavior* could be tested only by empirical research; such research was, however, not encouraged. One let oneself be dazzled by the terminology so that the driving forces behind a patient investigation of accurately delineated areas of observation became even weaker than before the book’s appearance. The contrast between the demands that were made on concept formation in the exact sciences on the one hand and those in semantics and related sciences on the other seemed to me even more drastic than before. Later on, Charles L. Stevenson’s *Language and Ethics* played a similar role; empirical questions and statements were confounded with results issuing from empirical research.

[10] That Carnap was not clear enough on this point is a daring statement that I should have documented. I shall here try to produce that documentation, without being able to say with certainty whether the question treated here was already decisively important to me at the moment of writing the treatise.

A thesis in Carnap’s “Testability and meaning” (1936a: 464) may be rendered as follows:

For all reasonable interpretations of T_0, T_1, \dots, T_n , T_0 is a cognitive heteronym of each of the statements T_1, T_2, \dots, T_n .

T_0 stands for “On May 6, 1935, at 4 P.M., there is a round black table in my room.” T_1 is “If on May . . . somebody is in my room and looks in such and such direction, he has visual perception of such and such a kind.” For T_2, \dots, T_n Carnap indicates similar wordings.

It seems reasonable to interpret the expression “cognitive heteronym” in such a way that Carnap’s thesis holds. The proof he offers for this thesis, however, seems to me unclear or untenable. Carnap says that T_1 “is a universal implication sentence: $(x) [(x \text{ is } \dots \text{ in my room and looks } \dots) \rightarrow (x \text{ perceives } \dots)]$,” which we may abbreviate in this way:

$$(1) (x) [P(x) \rightarrow Q(x)]$$

This statement, however, entails the very improbable assumption that the sign \rightarrow in a given logical calculus somehow equals “if . . . then.” Moreover, according to Carnap, this relation between \rightarrow and “if . . . then,” which is not further elucidated, must enable us to “abbreviate” T_1 as (1) without further ado. Which empirical science guarantees that there is such a relationship? Which tested or at least testable hypotheses are available bearing on the relationship between \rightarrow and “if . . . then”? Carnap seems to assume that he only carries out logical operations (a logical analysis) on his way from T_1 to (1). Meanwhile, he gives his opinion on empirical-semantical questions. His demonstration has a logical air; that it belongs to a not-yet-available empirical science is obscured.

Starting from (1) Carnap attempts to prove, by means of calculatory rules, that (1) is true even if $P(x)$ is false, that is, when it is not the case that “ x is . . . in my room and looks. . . .” His “proof” consists in, among other things, reformulating (1) as

$$(2) (x) [P(x) \Delta Q(x)]$$

This transformation implicitly presupposes the validity of a definition of the type $p \rightarrow q =_{\Delta} D \neg p \vee q$. Thereby the step from (1) to (2) is presented as a logical step and not as an empirically relevant operation. However, the question of whether statements of the type “if p , then q ” are in fact cognitive synonyms of sentences of the type “not- p or q ” is of the greatest importance for the conclusions he draws. If the expressions “not,” “or,” and “if-then” were not used in the same way as in the calculus chosen by Carnap, then his conclusions would be rendered invalid. Who, however, has studied the factual use of these expressions?¹²

The next step in Carnap’s argumentation consists in the observation that both T_0 and $P(x)$ might be false, namely in case there is neither a black table nor an observer in my room. Since in that case (1) is true but T_0 is false, (1) and T_0 cannot be synonymous; hence they are heteronyms. The same argumentation is applied to T_2, \dots, T_n .

Carnap seems to feel no need for empirical-semantical research to find out in which sense statements like T_0 and T_1 are used in the circles to which

all this is addressed. On the contrary, the fact that he explicitly presents his argument in a chain of five or more steps gives the impression that he would interpret reservations about his argument as doubts about the validity of his deductions, rather than about his empirical presuppositions. He renders the purely logical steps in the proof very carefully, but he does not mention the empirical-semantic presuppositions. That is, he seems to have expected logical-analytical objections rather than empirical objections. In my opinion, however, one has much more reason to raise empirically relevant criticism here than criticism that has no empirical relevance. It would be appropriate among other things to investigate the relationship between the use of the expression “if-then” in ordinary language on the one hand and in logical calculi on the other. Carnap’s argumentation is built up in such a way that he does not in my opinion make it clear that T_0 cannot be reduced to T_1 .

By the way, I do not believe that T_1 can or could pass for a reasonable interpretation of T_0 . That was perhaps not even the case among the representatives of the “usual positivist opinion.” This is only an assumption, however. A thorough argumentation would take us deep into questions of the history of philosophy and empirical semantics.

The translation from the ordinary language of T_0 and T_1 to the symbolic language of (1) and back would take place in a series of steps. In my lectures on symbolic logic, I have tried to formulate these steps explicitly.

[11] This statement and the whole paragraph in which it occurs are a good example of how an individual C can fare who wants to pull an individual B out of the swamp into which he has sunk in his eagerness to rescue an individual A .

I (individual C) wanted to rescue the logical empiricists (B) from the antiempiricism in which they had ensnared themselves in their attempts to free human beings (A) from metaphysics—and what is the result? It seems that in the heat of the moment I have sometimes offered unusually comprehensive and indefinite statements without sufficient justification—merely to prevent the logical empiricists from delivering general and unjustified statements in their eagerness to free us from the uncommonly comprehensive, indefinite, and unjustified statements of the metaphysicians.

Maybe I wanted to point out that the conditions for a “not complete re-

ducibility” were so weak and so loosely connected with offhand interpretation and with empirical testing that, say, the statement in Descartes’s mechanistic metaphysics would have to be assessed as “incompletely reducible” to “physicalist language” (in Carnap’s wide sense of this term), rather than as completely irreducible. In other words, the conditions for incomplete reducibility do not amount to a refuge from metaphysics (in the derogatory meaning the word has in Carnap’s text).

[12] The act of replacing a formulation (a hypothesis) by a more precise¹³ one I call insular (as against “continental”) when it makes no difference to the hypothesis, because too many different interpretation possibilities remain. If, for example, logs whose diameters are to be measured are put into a thermoregulator so that the temperature differences in the forest cannot influence the length of the steel measuring rod, or if one pays attention to the thermodynamic theory of the extension of bodies when formulating hypotheses about the relation between the diameter and the age of logs, then we are concerned with insular acts of producing more precise formulations. For the sources of error with which one has to reckon as a consequence of such things as the degree to which the form of the cut deviates from a circle, are so great that the variations in length of the measuring rod become relatively small.

If symbolic logic is used to elucidate a thesis as indefinite as the one we discussed in comment 10 above, then the result is likely to be merely an insular reformation unless attention is paid to empirical semantics as well.

[13] This and the next section are taken from a small, unpublished paper, “Physikalismus und radikaler Empirismus” (Physicalism and radical empiricism; 1937). Neurath advised against publication with the argument that it in part contains attacks on standpoints that he and Carnap have already abolished.

The expression “radical empiricism” is meant to designate a point of view that logical empiricism would probably have to develop after having passed from an antimetaphysical to an ametaphysical stage. In agreement with the opinion that the essential contribution of logical empiricism in philosophy (that is to say, apart from pure logic) consists in its having created a possible basis for discussion, I have understood radical empiricism as a kind of common platform for effective philosophical discussion. Thus I wrote in “Physikalismus und radikaler Empirismus”:

I am interested in “radical empiricism” as an arena for discussions about foundations research, as an instrument for analyzing the historically given philosophical and metaphysical questions. When one enters such an arena one cannot at the same time take along all one’s favorite theses. It will be hard to find anyone who is prepared to play chess with me if I have already chosen a position such that my adversary, if he is not of a quite exceptional stature, cannot avoid a checkmate within three or four moves. The invitation from the physicalists is of this kind. . . . If “physical” is to be eliminated, then “psychical” should be, too. If “spiritual” is abolished, then “material” should be abolished as well.

[14] If the philosopher’s role consists in something else than to rectify the special sciences, or to erect an addition to existing sciences, then a person who wants to do philosophy, that is, logical analysis, should keep away from psychologism.

In the text I have tried to show that Carnap and Neurath practice psychology under false colors, and that I cannot personally be accused of the same fault. I use the basic concept ‘behavior’ in a sense that is neutral with respect to the “mental-corporeal” contrariety. That form of behaviorism that does not rely on corporeal support I have called radical behaviorism. The creed that statements of behavior are more easily tested when one tries to connect them with psychology is founded on unacceptable philosophical assumptions: “[a]n accompanying feature is a medico-pharmacological philosophy of drawers—a philosophy that assumes that no object is really scientific unless it can be stored as a compound or artifact, like for instance layers of nerve and cortex tissue” (Naess 1937).

[15] The argumentation pertaining to this quotation may be easier to understand if one starts with the following analogous sentence:

The average income of authors may be simply and uniquely determined by addition of their individual incomes and division of the sum by their number.

When the required material has already been collected and processed, this sentence gives us essential information. However, when we are not in possession of any material, or when the statistical value of our observations has not yet been examined, this sentence is of no help in getting us started on the problem.

Here “the procedure we have used to obtain [the sentence in question]

and to test it” is the processed observation material; “the logical analysis” is the calculation, carried out according to certain arithmetical rules. This analogy enhances what I wanted to emphasize in the text: if we want to test statements, we shall need the empirical sciences, so as to procure reliable material about how these sentences are used and about their connection with behavior. The older as well as the more recent meaning criteria of logical empiricism and of operationalism seem to presuppose a high degree of intuitive knowledge in the field of semantics, and they also presuppose that intentions can easily be communicated.

[16] I have tried to treat this point in the discussion of occurrence analysis in greater detail in *Interpretation and Preciseness* (1953 [SWAN I]). The variety of meaning hypotheses that fit a given material on occurrences excludes all arguments that presuppose a single cognitive meaning or only a limited number of cognitive meanings.

[17] In my paper “Notes on the foundation of psychology as a science” (1948: 25 ff.), I have discussed the relation between theory and practice in research. In the terminology introduced in that paper, one can say that the *Encyclopedia of Unified Science* was supposed to render extant psychological theories partly as research programs and partly as theories with a well-defined “primary predictional field.” This means, among other things, that theories should be formulated in such a manner that their limitations come clearly to the fore. On the other hand, differences of opinion would in many cases disappear, for they often arise precisely because theories are ascribed a validity far beyond their primary predictional field.

Since concept formation depends on the very theories in which the concepts are to be applied, a better delineation of the claims of a given theory would also reduce the number of concepts that occur in several theories. The common psychological conceptual structure is pushed into the background. One then will no longer have a need for many of the very general concepts with which one tries to characterize the various psychological schools today.

[18] What is said here agrees with my objections to meaning criteria that are formulated in the form of theses and therefore lead to infringements on psychology, that is, to judgments on which psychological statements are meaningful and which are not (see comment 7). The encyclopedist ought to take the role of middleman between psychological theoreticians, not that of a judge.

[19] When research is understood as a type of human activity, this sentence can be restated as follows: "Absolutism of action does not justify absolutism concerning hypotheses."

The investigator continually has to act on the basis of priority lists resting on conclusions drawn from dubious *pro-aut-contra* deliberations. The time and the energy he has at his disposal are limited; the field of research is infinite in all directions. If he wants to obtain results, he will have to concentrate on definite tasks. This often requires a certain amount of painful resignation, which may lead him to overestimate the area he has chosen and the significance of his results. However, the fact that a certain investigator has made an absolute (final, unconditional) choice does not justify utterances about his choice being the only adequate one in the research situation in question.

[20] In this appendix, physicalism is interpreted as a recommendation about techniques of discussion designed to prove the unity of science. The formulations that are offered in this section are, however, much too pretentious to serve as such recommendations. My intention was to underscore the fact that physicalist, operationalist, and related endeavors can contribute to the advancement of the unity of science. It was not my intention to discuss the problem areas within which they might turn out to be suitable as means of encyclopedic exposition, or the degree to which they might be suitable.

[21] The term *trivialism* is intended to underscore the fact that the seemingly fundamental oppositions between philosophical or scientific schools can often be elucidated only if one chooses a nonphilosophical, non-technical point of departure. In an (unpublished) paraphrase of Nietzsche, I once wrote: "Long live Trivialism!! Physicalism = the lab assistant's absolutism. If physicalism is rendered in a humanized fashion, out of its ashes mighty Trivialism arises—the cult of trivial linguistic habits, trivial concept formation, and trivial modes of behavior."

[22] The encyclopedia should, I think, primarily contain a survey of human knowledge; that is, it should above all describe the best corroborated hypotheses. Second, it ought to give information about research programs and offer prognoses about the further development of research. I believe Neurath shared this opinion.

Should philosophy be allotted a place of its own in the encyclopedia?

When one understands the concept of philosophy the way I have suggested on page 4 of my *Filosofiens historie* (History of philosophy, volumes 1 and 2, 1980), then philosophy can hardly be said to contain corroborated hypotheses—at least if the “corroboration” has to satisfy requirements of some substance. Of course, philosophical problems and assumptions could be taken into consideration in the description of research programs and research prognoses.

Neurath’s attitude to philosophy and my own basically agreed on this point. However, when the practical work on the encyclopedia was about to begin, differences of opinion surfaced. A long series of statements that Neurath ranked with the scientific truths (*Realsätze*) of the encyclopedia ought, in my opinion, to be regarded as philosophical statements, or else they must be reformulated and given the form of nonphilosophical research programs. It seemed to me that Neurath wanted to construct the encyclopedia as a comprehensive exposition of logical-empirist philosophy (see his various contributions to the encyclopedia).

[23] By philosophy, something else is meant here than in my later writings. Here “philosophy” means about the same as “antiempirist philosophy.” This corresponds to the linguistic usage of the Vienna Circle, whose members revolted against both of the mighty trends that at that time asserted themselves in Europe: German metaphysics (Heidegger, Hartmann, Spranger, and others) and Catholic theology and metaphysics. They admired the sagacity and consistency of the spokesmen of Catholicism, but they opposed their postulate about the existence of truths “above” science. They regarded German metaphysics as a danger for clear thought and conscientious research, in fact, for all mental life. In the politico-cultural respect they enjoyed, both trends outweighed empirical philosophy, and this seems to have contributed to the use of “philosophy” as a synonym for “antiempirical philosophy.” In Anglo-Saxon countries, where the position of empirist philosophy is far stronger, this linguistic usage seems less natural.

[24] Here and elsewhere I emphasize that when one wants to further the empirical movement, one ought to proceed in a practical manner. The word *practical* is here used in the sense given to it in pragmatist and voluntarist philosophy. Research is seen as a process in which certain actions, in particular those by which hypotheses are tested, play a decisive role. I

wanted to express that such actions are more valuable for science than is linguistic behavior without strong links with these actions. Meaning criteria, operationalistic theses, and physicalism are examples of the latter behavior. Discussion programs and research programs are, however, closely connected with the process of research.

The theoretical elaboration of the form of empiricism formulated by the logical empiricists ought to entail the abolition of antimetaphysical counterformulations. Empiricism ought, in my view, to be ametaphysical. I wanted to prevent Neurath's politico-cultural struggle with the German metaphysicians from having philosophical consequences. For this might be to the detriment of empiricism—at least in the long run.

APPENDIX II: Remarks on the Empirical Movement

A thorough investigation of an object seems to require that the investigator be, at least at the start, connected with the object by strong interests of a biological, social, or metaphysical kind—to use a triple classification taken from P. W. Zappfe (1941: 62).¹⁴

The history of geometry offers good examples of the significance of these three kinds of interest, not least the metaphysical-religious interest. In the sect of the Pythagoreans, the study of geometrical figures was often seen as the main task of its members. Thereby this study was made into a religious profession. Later, geometry was detached from metaphysical problems, although the latter continued to play a role as sources of inspiration. For the development of geometry it was now important that Greek mathematicians could devote themselves entirely to the study of geometrical relations without concern for the practical applicability of their discoveries. This field of research had acquired a value of its own.

The history of chemistry, too, offers numerous examples of the rule that science flourishes when interests external to genuine research recede into the background, that is, when the object of study and the research itself are ascribed a value of their own. In the exposition of the prehistory of scientific chemistry, one frequently employs terms that indicate the extrascientific center of attention. Thus one speaks of the period of alchemy (A.D. 400–1500) and of the period of medical or pharmaceutical chemistry (A.D. 1500–1700).

The same holds for the history of historiography. Originally, it was

mainly an instrument for the glorification of princes, dynasties, nations, and political and religious movements. Interest in the course of history and in research as such eventually acquired a greater significance, and historiography thereby developed into a source of knowledge. It has turned out to be possible to combine strong political, religious, or other interests with a high degree of objectivity in the treatment of historical material. People embarking on historical research to justify standpoints already taken have often been swept along by the dynamics of their research. They have felt obliged to give up the standpoint to which they were originally strongly committed. This they have not experienced as a loss but as an enrichment. As research workers they have—sometimes for the rest of their lives—engaged in an undertaking that exceeded their range of vision, but in which the efforts of an individual have their own independent worth.

The first steps in new fields of investigation can often be taken only when one has overcome the resistance of those whose interests are endangered by an expansion of research. Resistance sometimes arises because the expansion is taking place in an area in which certain people believe they possess pure knowledge, rather than in an area in which we all admit our ignorance. Here the development of chemistry may serve as an example. Any number of people, including several chemists, believed that they knew that organic substance could not be compounded from inorganic material. This conviction obstructed research in organic chemistry.

A further reason for resistance is to be found in the ideological importance of certain convictions. When the investigator does not confirm the results commonly held to be established knowledge in his culture, he must expect to be accused of destroying cultural values.

For all that, the analysis of already acknowledged parts of human understanding is an essential factor in preparations for new research efforts. If we do not have a strong and lasting conviction that our knowledge has defects and gaps, then we shall hardly be able to muster the energy needed for a long and intensive period of research.

The empirist tradition in philosophy is, in the main, in character with the expansion of research and therefore in opposition to attempts to portray human knowledge as conclusive and exhaustive. It is destructive inasmuch as it tries to dispose of everything that impedes free research.¹⁵

Whoever wants to participate in improving the conditions for a further

expansion of research cannot avoid feuds with points of view that seem to obstruct it. In the heat of the moment, one may easily succumb to the temptation to formulate general statements uncritically and to ascribe to them a much too high degree of certainty. This has a negative effect on motivating research in fields in which research is needed.

The brilliant contributions of logical empiricists in many border areas in contemporary science were partly inspired by a strong confidence in their criteria for cognitive meaningfulness, in physicalism, in symbolic logic, and in encyclopedic procedure. This confidence was exaggerated. Besides, it had a negative effect on motivating the investigation of empirical-semantic questions, the relationship between natural and symbolic languages, techniques for discussion as instruments of an empirically oriented philosophy, and so forth. On the other hand, if one invites others to employ a certain technique of discussion, then it is not necessary to rely on the general assumptions of the logical empiricists. One can further the empirical movement just as well by trying to bring about a positive motivation concerning investigation of the problems in question.

From the point of view of the empirical movement, it is important to distinguish between enthusiasm for science and enthusiasm for research. Enthusiasm for science easily leads to overestimation of available knowledge so that problems that presuppose doubt as to the foundations of this knowledge are pushed back. Enthusiasm for research as such counteracts this tendency. To embark on a research program, one has to make a series of assumptions that serve as provisional working hypotheses and that are changed and improved along the way. It is seldom useful to the investigator to believe that his own assumptions have a higher degree of certainty than what is strictly necessary for a good working hypothesis.

The relation between enthusiasm for science and enthusiasm for research can be elucidated by investigating how certain people react to parapsychology. Enthusiasm for science as we know it can elicit aversion or above-average scepticism toward parapsychological experiments (for example, those of Rhine et al.), although these experiments are hardly methodologically inferior to psychological experiments that are recognized as up to standard. Those who value research highly will find the possibility of a revision of our physical knowledge as a consequence of parapsychological experiments a particularly enticing prospect.

The belief in science as we know it today can impede the progress of research in various ways, such as by allowing the idea to arise that the unknown corresponds to the white spots on a map of the world. Even when we imagine such spots to be very large—even when we imagine a globe on which only a tiny green island has been inscribed with a bit of blue sea around it, everything else being left white—I believe the analogy to be false in a particular respect. The green island would form a part of the surface of the globe whose area could be determined in relation to the globe. Also, in this picture one would imagine that the island corresponds to a bit of definitively secured knowledge.

A system of scientific classification can also turn out to be disadvantageous to the expansion of research, namely, if one assumes such a schema to be something more than an ad hoc classification, adapted to certain technical bibliographical needs and the like. This especially holds of the classification of the sciences, which Auguste Comte took as fundamental in his *Cours de la philosophie positive*. By giving us the moments of birth of the sciences separately and by a system said to encompass all objects of research, he pretends to be able to place future research within certain areas. Thereby the unknown is in a sense encircled, much as the white spots on the map of Africa when the whole African coast had become “known.” For example, psychology as a science is represented as firmly delineated, so that unexplored fields can only be situated inside. The same goes for other sciences. This idea of an eternally fixed system of main sciences can hamper research, for example, when the research program depends on working hypotheses that implicitly go counter to the classification in question.

Logical Empiricism and the Uniqueness of the Schlick Seminar: A Personal Experience with Consequences

In what follows I shall speak about many phenomena, but what I wish to convey more than anything else are the positive aspects of the rightly famous seminar headed by Moritz Schlick in the years before he was shot on the stairs of the University of Vienna in 1936. The characteristics that I shall describe made the seminar unique. I have taken part in a wealth of good seminars before and after 1936, but my experience as a participant of that seminar makes it, for me, stand out as unsurpassed.

When for the first time I entered the room where the seminar was held in 1934, I did not know what had been happening there. I had heard nothing about the seminar or about logical empiricism in general. It took less than an hour for me to understand that something very special was going on there. In the autumn of 1935, when I left Vienna, I did not yet realize how much I had been influenced.¹ It is only recently that it has become clear to me what I found so deeply inspiring—what touched both my heart and my brain. I shall permit myself to trace how the experience affected my later philosophy.

The seminar was headed by a “professor ordinarius,” a prestigious title in the context of central Europe, but Dr. Friedrich Waismann was the actual leader. Both men were culturally well established, mature scientists and philosophers. There were other well-established personalities. The first feature to be mentioned is the participation of mature, independent, established personalities. The second feature is the unmistakable diversity of

This article was reprinted with permission from *Scientific Philosophy: Origins and Development*, edited by Friedrich Stadler (Dordrecht, Netherlands: Kluwer Academic Publishers, 1993), 11–25.

their characters. Obviously, not only from what they were saying, but from their body language and manifest attitudes in general, they had to have different opinions and this would have to color their philosophy.

With the third feature, things start to be interesting: both the core members of the seminar and the visitors—about ten people—were seriously engaged in one and the same great undertaking. There was an atmosphere of eager cooperation. Something very great was being built, and any contribution, however modest, was appreciated. There was room for all. Opinions differed, but then it was essential to ask, Is the difference serious? exactly how serious? Perhaps minor, perhaps all to the good: there ought to be no *Gleichschaltung*.

The next two features to be mentioned concern a central phenomenon: the character of communication in matters of philosophy and ideology.

Compared with terminology in, say, physics and chemistry, terminologies in philosophy tend to be vague, ambiguous, unclear. Or to be more precise, the words and sentences may be unambiguous and clear to the speaker (the “sender” of the communication) but not to the receiver. How did the seminar tackle the inevitable conflicts arising from this situation? Let me give an example.

A participant puts forth an opinion, using a sentence *T*. A second participant, probably thinking the opinion is not tenable, speaks up, “Würden Sie (würdest du) die Formulierung *U* akzeptieren?” (“Would you accept the formulation *U*?”). A special opening gambit was invented by the young Walter Hollitscher: “Das ist vielleicht nicht eine glückliche Formulierung . . .” (“That is perhaps not a happy [fortunate] formulation”). It is implicitly clear that the second participant puts forth *U* as an expression for the same formulation that the first participant tried to express by *T*. The first participant is *invited* to give his opinion about a somewhat different formulation that perhaps would make listeners better understand what he wishes to convey. It is mostly also implicitly suggested that if the first participant rejects *U*, the second would tentatively declare that *T* expresses for him an opinion he does not find tenable, but that what *U* expresses he can accept as a tenable opinion or hypothesis. If the first participant rejects *U* as an adequate expression, he may himself substitute *V*, a third sentence, for *T*, and the serious “game” would continue.

What struck me as *mustergültig* (worthy of being a model) about this

procedure was the effort not to declare *lack of agreement* until careful verbal investigation had eliminated the undesirable effects of terminological idiosyncrasies, *and* the choice of a conciliatory, building-up-the-other way of clarification. “I disagree” has a tendency to awaken defensive countermeasures, often leading to unfruitful discussions—even a hurt ego, or at least a lust to win an argument. A careful procedure makes it more likely that when disagreement is declared, it is a real disagreement, and an honest one.

The fourth communication feature I wish to mention is the care taken not to use that-sentences like “So-and-so has the opinion that such and such.” Such sentences imply unambiguity and the general, agreed upon clearness of the “such and such.” Instead, expressions like “So-and-so says *T*” and “So-and-so formulates his opinion this way: . . .” are used. It is not taken for granted that the group has already found an adequate expression of one and the same opinion.

(My later extensive use of the term *formulation*, rather than *sentence*, is probably influenced by the Schlick seminar!)

Now, the fifth feature of a way of communication in philosophy and ideology is the most radically important. We often search for words to express our thoughts. We imply that the thought is already there, but that it is difficult to find a completely adequate and accurate verbal expression. Perhaps less often, we wonder what exactly we meant, if anything, when we said such and such. The above-described features of communication in the Schlick seminar made it completely natural to doubt that we meant something very definite when we listened to our long strings of words. Fixing the attention on words, phrases, or sentences, but not that-sentences, made it easy to admit at least to ourselves that we were not quite clear in our heads—that we in a sense were only vaguely aware of what we might be talking about. Our talking was like our walking: we did it in the habitual, familiar way, practically like automatons. Very rarely did it reflect clear thinking.

Suppose the question is whether a theory in science can be falsified. Some of us were, so to say, instinctively opposed to the possibility of falsification in any strict sense, but what did we mean by “strict sense”? by “theory”? by “(practical, theoretical, empty) possibility”? If we were talking about what usually was classed as a physical theory, there were disconfirmatory instances—but what more? Every definite series of observation sen-

tences rests on indefinitely numerous assumptions that are not all—or perhaps none—strictly speaking verified. Did we ever mean anything definite by falsification of a theory? Karl Popper did not clarify what he meant—so it seemed to us.

The often unsuccessful search for what we ourselves meant by things we had said—perhaps said 100 times!—resulted in a kind of humility. How could other people, doing research with a completely open mind, assert that they knew exactly what they meant?

A few years later, I had the opportunity to talk seriously with one of the very few internationally well known Norwegian masters of mathematical logic—Thoralf Skolem. I asked him whether he was sure he knew *exactly* what he meant when he wrote in his articles that “this is now proved” or some similar phrase of the kind *quod erat demonstrandum*. To my great disappointment, he answered yes—after some hesitation, I admit. I thought the history of mathematics showed how it often seemed clear after some years or centuries that those who had proposed criteria did not realize that these were unclear, ambiguous, or, strictly speaking, not universally applicable. Fallibility seemed to be clear in questions of what one means by *proof* and by other central metamathematical terms.

Through experiments I later tried to assess the *definiteness* of intended meanings among students of the exact sciences. How did they interpret “The Earth is surrounded by a gravitation field” when they heard the sentence in a speech I gave? They were offered twenty interpretations. The answers I liked best were the *nescio*-answers, the “I do not know” answers. However, most answers (more than 150 out of about 200) revealed that the respondents thought they knew fairly well how they interpreted the sentence. The Schlick seminar certainly was apt to spur a lively interest in the limitation of human definiteness of intention. In philosophy and ideology it takes more courage, it seems, to admit this than it takes in the exact sciences. The reasons are not without interest.

These five features of communication can thrive only among people with a certain—what I am tempted to call—Gandhian nonviolent approach. One must be able and willing to look for interpretations that make one’s opponent reasonable, not just those that make him unreasonable, ignorant, or stupid. In the late 1960s, when seminars on philosophy of science were held with a strong representation of students of the Frankfurt school,

these members tended to think of discussion in terms of confrontation rather than cooperation. The Gandhian traits smacked of what they liked to call positivism. Carnap would have had no chance to be heard! It is easy to be mild and fair when you are not passionately involved. Carnap and others combined intellectual passion with a Gandhian approach to communication.

To my sincere regret I find today that nearly all of the most active participants of the seminar in 1934–1935 are dead or ill. Therefore, I shall now convey a selection of my impressions of the participants, using my own fallible memory as a guide. Because of my many new interests since the 1930s, I have not read the impressions that others have published.

About the established leader of the seminar, Moritz Schlick, I have little to say. Few of us had any access to his private life. We perceived him as somewhat distant and we called him an aristocrat. He did not talk very much. When a discussion led us into an impasse, he might ask, “What would Wittgenstein say here?” When somebody offered a quotation from Wittgenstein’s writings or from his remarks in seminars or private conversations, it was clear that only very, very clever interpretations could be accepted. Like interpreting Ibsen in Norway.

It was the expectation that at least Friedrich Waismann would have an answer to Schlick’s difficult question. He was the “leader in action” of the seminar, and we all acknowledged his expertise on that slightly mysterious subject—the (correct) Wittgensteinian view. He and Schlick were the only active members of the circle who would totally advocate and defend Wittgenstein’s view—when they thought they had grasped it firmly. The fearful question posed by Schlick normally was followed by silence at first. Then Waismann would answer, but tentatively and hesitantly. Once someone suggested that a letter should be sent to Wittgenstein; but Wittgenstein was enigmatic and not a character one could expect to answer straightforwardly. We did not know it then, but at that time he himself was painfully rethinking where he stood. This whole situation exasperated Waismann. Perhaps that was why I gradually came to see him as a tragic person, humble and not quite knowing how to handle his life and his position in philosophical disputes.

His seriousness and humility manifested themselves in a touching

way. I was going through an intense psychoanalysis at that time. My analyst, the well-known Dr. Edward Hitschmann, wished it to be a *Lebranalyse* and arranged to send me to Pötzel Psychiatric Clinic wearing a doctor's outfit and being introduced as "Dr. Naess from Norway." One of "my" patients was a highly educated woman who, prodded by my scepticism, defended for hours and hours the view that President Franklin Roosevelt had tried to poison her. She brilliantly defended her system—it was truly impressive. Speaking as we often did in the seminar about coherence, I said in a private talk with Waismann that a paranoid schizophrenic seemed to satisfy the ultimate requirements of coherence better than he did. There was no smile on Waismann's face. Yes, he said, but then he wandered into difficult, seemingly depressive trends of reflection. Of course, I did not seriously mean what I said: if Waismann had been in bed with nothing else to do but answer my question, he would have managed to be very coherent, even in the formulation of a sophisticated methodology that gave room for extensive doubt and uncertainty. My patient had no doubt in relation to a long series of coherent arguments and conclusions, but that did not imply superiority. She had a definite dogmatic system at her disposal, whereas Waismann was basically bewildered, but not less coherent from a systematic point of view and certainly more coherent from a metasystematic viewpoint.

Schlick and Waismann were of a different generation than I, and I had more informal, daily interaction with some of the younger active participants.

Among the prominent young members of the seminar was Joseph Schächter. His work *Prolegomena einer rein kritischen Grammatik* contained views that were considered rather un-Wittgensteinian. He also had difficulties with "proper" appreciation of Russell and his "material implication."² It was not easy for him to publish his manuscript. I found his position unenviable. In the same category was the Polish-German logician and philosopher Rose Rand. She, like the others, considered Wittgenstein to be a genius, but she was of the opinion that he nevertheless was unable to express his opinions adequately. The style of the *Tractatus* she considered to be a manifestation of helplessness rather than of deliberate choice. Later she gave lectures on Wittgenstein at Cambridge, but her consistently hypercritical comments contributed to the termination of her teaching. She also

suffered a serious nervous breakdown. She liked to talk to patients in the Pötzel Clinic, considering herself a borderline case.

Listening to Schächter, Rose Rand, and others, it was understandable that I developed an ambivalent attitude toward the texts of Wittgenstein. Gottlob Frege and the Wittgenstein of the *Tractatus* seemed to belong to a vastly different tribe than that of Malinowski, my hero in the philosophy of language. Wittgenstein was a genius, but what follows from that? Nothing.

Outstanding in the clarity of his statements in the seminar was a man only a couple of years older than myself, I presume: Walter Hollitscher. His contributions to the seminar were always short, firmly expressed, and wonderfully clear. The prevailing view of the importance of language for philosophy got a marvelous expression. He invented the phrase “Es ist in der Sprache nicht vorgesehen” (“It is in language not foreseen”). The tendency that he opposed was to declare certain questions or answers in philosophical literature meaningless, and to bolster this view by recourse to beliefs in certain fundamental traits of syntax or semantics. Language could not be used for the purpose some philosophers had in mind. The philosopher pressed the language beyond or below its capacity. New theories of previously unheard kinds could be formulated properly, for example, that of general relativity, but there were limits that could not be transgressed without meaninglessness as a consequence. Hollitscher was remarkable in softening the “meaningless” dogmatism. More strange than remarkable was his ability also in managing to a large degree to combine membership in the Austrian Communist Party with a complete rejection of dialectical materialism—as *sprachlich nicht vorgesehen*—in its main features. On the other hand, he found hope for psychoanalytical theory. It could be reformulated in a scientifically acceptable terminology. I have talked about Walter Hollitscher at length also because he represented so well the high ethical standard of the discussions. However, he did not publish much, remaining in the background.

Whatever my philosophical disagreement with some of the main tendencies in the seminar, I wished to learn as much as I could from the proceedings in which I participated, and I was treated on a par with the others in spite of my dissonant views.

In the circle was a young man, Tscha Hung, from a country even farther away than Norway. Always cheerful and well-meaning, he showed in his attitude a deference, even a humbleness, markedly different from my

tendency to be as interested in proclaiming disagreements as noting agreement. His lifelong attachment to Moritz Schlick and Schlick's point of view I found and still find touching. This is not to underrate his independent thinking and achievement as a professor in Beijing in making the analytical trends known in China.

It was a habit of circle members to meet for hours in one of the cheap coffeehouses. There the discussion was even more lively than in the seminar. It was not easy for me to break into these fast-moving discussions. Sometimes I would suddenly and unexpectedly just say "Im Gegenteil" ("On the contrary"). There would then be a second's astonished silence and I could proceed at leisure. It was typical of the atmosphere that my youth was not at all an obstacle to complete recognition.

The seriousness, honesty, and persistence of Carnap in debates I had with him in Vienna and later in Los Angeles, where I stayed in his home for some time, left a profound impression—perhaps especially because he practically never found any reason to change his opinions on any matter whatsoever. He tried his best to follow my way of thinking, even if he did not expect to profit from it in his own research. He never showed the slightest impatience. (I did.)

On special occasions the core members of the Vienna Circle discussed the plans of the forthcoming International Congress for the Unity of Science. Here Otto Neurath was the central personality. He looked upon Carnap as highly impractical and excessively fond of long, logical derivations. Moreover, he viewed logical sophistication somewhat cynically, declaring that Franciscan monks were excellent logicians, implying in a sinister way that perhaps formal logic could accommodate Catholicism better than it could accommodate the scientific attitude. I shall not go into what was happening at these high-level conferences. The last one that was planned—to take place in Oslo in 1940—could not be realized because of World War II. Otto Neurath applied to the Norwegian authorities for residence in Oslo but was rejected by an anticommunist official at the Norwegian immigration office. What a shame! I shall now leave the account of personal experience and proceed to more abstract matters.

When I interpret a philosophical text, my point of view is that of a lawyer interpreting a will. Grammatical failures, strange uses of words, mis-

spellings do not count when one tries to find out exactly what the author of the will intended to convey in his will. If he calls his wine cellar the library, that is okay, if it can be established that this was the habitual way of talking in his family. Similarly, if a philosopher has strange ways of expressing certain opinions, one of the tasks of the historian of philosophy is to try out reformulations better suited to present his or her opinions. On the other hand, we may look upon the text as a musical or mathematical score and see which interpretation might be most interesting given certain purposes. The later texts of Heidegger, for example, have been freely interpreted by some environmentalists and found very useful. The logical empiricists, however, were too attracted to the exploration of one definite model of language, namely calculi with sets of formation and transformation rules, to be interested in the more empirical investigations of philosophical texts as presenting ordinary ways of talking. The ordinary ways are full of metaphors, pictures, unscientific phrases—as are those of philosophers through the ages.

Carnap seemed to accept a presupposition that he had philosophically adequate knowledge of what ordinary words and sentences of his mother tongue meant, including the words *true*, *probable*, and *certain*. Or at least he presumed that we have sources within ourselves of such knowledge: by painstaking reflection we should be capable of formulating that knowledge clearly. Some of it would be, in psychoanalytical terminology, *vor-bewußt* (preconscious). It can be made conscious without being hindered by forces of psychological repression.

The American philosopher Charles Morris embraced a sort of empiricism that offered logical empiricism a kind of alibi. He introduced the term *pragmatics* so that he could point to a trilogy: syntax, semantics, and pragmatics. What I was doing, Carnap said, was pragmatic, and he seriously wished me success, placing me in that coffer. What Morris was proclaiming, however, was empiricism, not pragmatism. I used social science methodology to investigate the various usages of *true*, *certain*, etc. For example, I offered subjects ten glasses, saying that they contained weak solutions of certain well-known substances. Could they please tell me what they smelled? “Are you certain?”, “Are you absolutely certain?”, “Do you truly smell anything?” Their answers were made starting points for an interview in which they copiously used the terms *true*, *certain*, etc.

Actually what they strained themselves to smell was pure water (which

was still available in Norway in 1936). How could the logical empiricists boast about a scientific attitude when they relied so much on intuition when speaking about the use of words?

If one is thoroughly imbued with respect for spontaneous experience in its immense richness, then it occurs to me that the interpretation of a text should be much more difficult than it seemed to be for Carnap. The words and sentences of our mother tongue have been judged vague and ambiguous since the time of Aristotle. Therefore, any texts that make use of daily-life vocabulary or define words in terms of everyday vocabulary will be open to a variety of significant interpretations. Being very much impressed by, and fond of, the Latin text of Spinoza's *Ethics* from the time of my school days, I did not entirely look down upon vagueness and ambiguity, and I thought that when we interpreted a text, we should formulate different *tentative* hypotheses about what the author might have intended to say. I did not believe that the members of the circle really had the preconscious knowledge they thought they had according to their fundamental presuppositions. Social science methodologies were needed.

Carnap willingly and patiently talked with me about this. I have never again had the opportunity to meet anyone with such wide learning and such basic humility. Somehow, though, he retained the conviction that, in the last analysis, his own interpretations were at least the only philosophically important ones. This was especially evident when it came to assessing the significance of Alfred Tarski's truth theory. This theory was an astounding victory of symbolic logic with great consequences for formalization. It mostly hits the nail on the head when one asks for precizations of the sentence " x is true" when x belongs to the assertions of a scientific text. It has been popularized through the following: "the sentence 'It rains' is true if and only if it rains." Carnap admitted that there was of course an important way of using the word *true* that was not covered by Tarski's definition. One could say, for example, that " x is a true friend." Then, however, one could also form an application of Tarski's theory: "' x is a true friend'" is true if and only if x is a true friend." By chance my master's thesis was about various usages of the term *true*, and for me it was important to stress that Tarski's definition applies clearly only to a subgroup of occurrences. Moreover, other groups are important in scientific texts, and relevant to pertinent philosophical questions focusing on the term *true*. Tarski himself ac-

knowledgeed later on a postcard he sent me that I might be right in what I said, but that his theory did not necessarily pretend to cover more than one way, a fundamental way of using the term from the point of view of logic.

Carnap detested Heidegger both for his politics and for his literary style. I agreed. One of the sentences that provoked him was the notorious “Das Nichts nichtet.” I said that Heidegger perhaps intended to assert something fairly definite by this atrocious utterance. Carnap repeated again and again that if (and only if?) Heidegger had stated his rules of formation and transformation, the sentence would be acceptable as meaningful. In philosophical texts, however, there is an abundance of “unacceptable” but potentially meaningful sentences.

I am today tempted to refer to a famous sentence of the relativist J. A. Wheeler: “matter tells space how to curve, and space tells matter how to move.” What would Schächter and Walter Hollitscher say about this sentence? I might suppose Schächter would say that the sentence violates logical grammar; Hollitscher, that *es ist in der Sprache nicht vorgesehen* that matter and space tell anything whatsoever. The supposition is wrong, however. The sentence is obviously meant metaphorically, and Wheeler can point to a certain set of equations and say, “This is what I mean in all seriousness. Any complaints?” Because general relativity enjoys top scientific status among the logical empiricists, they would treat Wheeler politely. To compare a Wheeler sentence with a Heidegger sentence would be seen as tasteless.

Empirical research might end with the tentative hypothesis that Heidegger did not mean to assert anything through his famous sentence, but that would only be one hypothesis among others. Carnap agreed to that, but did not find it very interesting. Roughly speaking, Carnap did, but I did not, believe in *Die Wende der Philosophie*, the syntax-oriented turn of the philosophical tradition. Carnap would listen patiently, but later, when I had included a description of his and of Heidegger’s philosophy in one and the same volume, he would complain seriously, as if it were an unfriendly gesture on my part. How could I, as an old friend, do him such an injustice? For Carnap, Heidegger was not only both philosophically and politically abominable, but also expressive of an influential and deplorable cultural trend. Carnap continued to write within his frame of thought but expressed his belief that I should continue my empirical investigations.

The younger generation was headed, one may perhaps say, by Carl G.

Hempel, another superbly clear philosopher with rare pedagogical talent. At an International Congress for the Unity of Science his elegant, formal-logical lecture was greeted with applause worthy of a great artist. A Polish logician contributed with logic on a high formal level, devoting most of his time to sophisticated, but microscopic, issues of notation. The trend was not going in the direction of combined logical and empirical research. Why exactly should very special formal-logical investigations be considered more important in philosophical research than empirical investigations? Neurath was slightly apprehensive; I was genuinely sorry. The task required the combination, and also the application to crucial social and political conflict analysis.

Otto Neurath was the leading spirit in what might be called the movement of logical empiricism. It is sometimes forgotten that analytical trends in philosophy after 1945 never had this color of a movement. That includes the groups around Willard Quine.

It is well known that Neurath liked to compare the trend from Ernst Mach to the Vienna Circle and then to the international logical empirical perspective with stages in the development of the movement around the French Encyclopedists. It was therefore natural that he should propose a kind of encyclopedia, the onion-shaped *Encyclopedia of Unified Science* demanding the collaboration of hundreds of people.

In a social movement, the moderate level of preciseness that Neurath represented, but Carnap disliked, would be absolutely necessary. The encyclopedia would have to be understandable to a fairly large sector of the population. It would not be enough to reach only people with very high formal educations. Neurath introduced a word that I found important: *Ballungen*. In English, one would perhaps say “sticky formulations.” They could be interpreted in slightly different ways, being in some sense elastic and adaptable to a variety of situations. It is a pity that the concept of *Ballungen* was not taken more seriously within the movement. It may have inspired my term *point-of-departure formulation* (T_0), the “target” of different analyses.

Carnap, of course, had no taste for *Ballungen*. He preferred to jump from the vague and ambiguous to the superbly precise and rest there. Neurath was elastic, proceeding from the vague and ambiguous as point-of-

departure formulations to more precise ones and back again. Every very precise analysis or reformulation leaves something out. Not a single more precise formulation would do in the long run, only a set of them: T_1 , T_2 , . . . T_n . At least this is how I believe I may have interpreted him.

An eminent psychologist, Egon Brunswick, roughly agreed with the main position of logical empiricism, and eventually it was decided that I should, together with Brunswick, write on psychology as a science. It turned out, however, that we disagreed about how this should be done and I left the task to my friend Egon. The organization committee of the encyclopedia was not sufficiently strong to press the authors of the monographs to complete their contributions. Nor did the authors agree on how to spell out “the foundation of the unity of science.” This seems to me to be one of the many reasons that “the second volume of the Encyclopedia ran into many difficulties, and . . . the studies by Federigo Enriques, Jan Lukasiewicz, Arne Naess, Louis Rougier, and Louis Wirth never appeared” (Morris 1960, 520). Such people are not easy to handle and be made to work together! They had been persuaded to write monographs but were not quite clear, I suppose, on exactly how to proceed. I am sorry to say it, but Neurath’s plan for an encyclopedia ultimately consisting of 260 monographs in twenty-six volumes plus a ten-volume *Visual Thesaurus*, although splendid, was quite unrealistic.

Diderot, in the “period of enlightenment,” found the time ripe for his twenty-six-volume *Dictionnaire raisonné des sciences, des arts et des métiers*. The economic and sociological insights of Neurath did not suffice to make him (or anybody else) see the time ripe for a second world war, a sterile Cold War, a mindless consumerism, with resulting waste of resources, and a population explosion threatening the richness and diversity of life on Earth. Being already heavily influenced by Mahatma Gandhi’s nonviolence and metaphysics, I did not find Neurath’s vision too ambitious. Dr. Hitschmann gave me articles that Neurath had published, one with the dedication “To Arne Naess who wills the great (*dem Großes Wollenden*).” Later my German colleagues called me what I cannot translate: “*der norwegische unverbesserliche Weltverbesserer*.” If Neurath had lived on for another twenty years, we could have worked together in the peace movement. We largely understood each other. Even his notorious *Index verborum prohibitorum*—asking us to refrain from words suggestive of subjectivist metaphysics—I

found acceptable in spite of my wise friend Philipp Frank's exasperation and ridicule.

Looking back, I feel sorry that the combined analytical and social initiative of the logical empiricists petered out. It constituted in the 1930s a cultural force and a threat against fascist and authoritarian regimes in general. The authoritarian Austrian government did not underestimate this threat, and the newspapers—which on the whole were on the authoritarian side—expressed relief when Professor Moritz Schlick was killed on the doorstep of the university. Logical empiricism was proclaimed to be a blot on Austrian culture. I was asked to protest against this in Scandinavian newspapers, but I regret today that at that time I did not feel able to engage in public debate. When Quine and others took over the analytical leadership, the movement was largely robbed of its social and political aspects. Applied logic suffered. At a meeting in one of the branches of New York University I gave a talk with the title “Why has logic made so little progress in this century?” In the audience were some of the most creative symbolic logicians. What I meant was, Why has logic as a social enterprise made so little progress in social and political debates? The logical empiricists took applied logic seriously. In addition to the personalities I have mentioned in this connection, Zilsel must be remembered. After the hot war, that is, during the Cold War, and during the Vietnam crisis, applied logic seemed to be looked down upon by many eminent logicians. Applied logic was conceived as inherently second-rate and also unphilosophical insofar as it often required empirical research, for example, investigation of political slogans and political argumentation patterns. There was a tendency to stay away from the use of social science techniques in the investigation of actually occurring transitions from premises to conclusions. The International Congress for Unified Science in Oslo in 1940 would presumably have dealt extensively with such theses, which both Neurath and I considered crucial: the empirically relevant issues. It would have included a variety of applications of logical analysis, but it would scarcely have changed the general direction of development within logical empiricism.³

The logical empiricists were broader and deeper in their outlook than in their professional philosophy! Or, to be more careful: what was likely to be

the picture of their philosophy internationally was that of a somewhat narrow, spartan, pedantic, and cold kind of—metaphysics. They were to be conceived as *Lichtlöscher* (light extinguishers), restraining the human spirit: basically positivists akin to Auguste Comte, devoid of imagination.

From the point of view of the history of ideas, we can now see that the “antipositivist” current was stronger both before and after the war than the current of enlightenment that the logical positivists tried to help gain power. Neurath’s planned twenty-six-volume encyclopedia had to remain a dream. “Had to”? Of course not interpreted as historical necessity, but if we compare the conditions prevailing at the time of the multivolume French encyclopedia with those of the pre- and postwar years, Neurath’s chances were close to nil.

During the Cold War there was a strong—but not strong enough—“third way” that brought some people all over the Western world together. The personal philosophy of the logical empiricists was well adapted to the main tenets of the third way. Their philosophy as judged from their writings and even their preferred way of speaking was counterproductive, however. They succumbed too often to an unpalatable “scientific” jargon, using a metaphor, “Unified Science,” as a core slogan. (Why “unification”?) Their dream deserved a less narrow slogan. Their younger generation had little chance to make headway on the great international scene, and they were perhaps less strongly motivated to fight.

How can I speak with confidence about the contrast between their narrow professional and their broad and deep personal philosophy? What are my credentials? I have one: my experience; the way I was accepted in 1934, and the way I was invariably treated later.

I entered the shabby seminar room of the Schlick seminar in 1934 with a peculiar philosophical background. When I was seventeen I had become deeply fascinated by both Spinoza’s *Ethics* and Whitehead and Russell’s *Principia Mathematica*. It was impossible for me not to talk and talk about those texts. The first chapters of the *Principia* were enough for me to become a friend of symbolic logic and a permanent user of *simple* propositional and functional calculus—even using it to make Spinoza’s conceptual structures clear to me. The *Ethics* has remained for the rest of my life the supreme paradigm of philosophy. There has been no *Wende der Philosophie* since the *Ethics*! In philosophy of language I appreciated Ogden and

Richards's *The Meaning of Meaning* and was completely charmed by Malinowski's view. The essence of his view—using *Ballungen* here—may be suggested through these formulations: “You mean speaking? Just fragments of behaviors (*Verhaltensweisen*).” Imagine two people in a canoe—preferably Polynesians—one rowing, the other catching fish. Working together, they use mainly one-word sentences, rarely descriptive, mostly with strong signal function. The scientific way of talking has basically this function, I thought. Pure descriptive function does not exist. I was, in short, a member of what was called “the Malinowski tribe,” applying his view to both the *Ethics* and *Principia Mathematica*. From William James's *The Varieties of Religious Experience* I learned a wide sort of empiricism. One should not take offense when people use terms like *God*, *substance*, and *immortality*. They could be translated in many ways, and important experiences elicited the use of the terms.

It was an unforgettable experience how Carnap reacted when I provocatively said that in the debate between James and Russell, James was nearer the truth. Did I spit in a church? Carnap looked seriously and inquiringly at me as he slowly answered, “Y-e-s? Do you think so?” Insofar as I was in a church, I was in a widely compassionate one. Most of what I said and obviously really meant, but which was not appropriate to say in their jargon, Carnap and Neurath found not only palatable but consistent with their philosophy at a deeper level. Russell revered Spinoza; Carnap and Neurath were less positive—they did not see a way to interpret the bulk of the formulations of the *Ethics* so as to make them consistent with their daily professed methodology and epistemology. In a way they envied me. Of course, Malinowski's view as “pragmatics” was not only legitimate but of great importance. Go on with your investigations, they would say. When they invited me to write a monograph on psychology, they completely trusted that it would fit in well with the encyclopedia. My first draft was very tolerant toward many contemporary competing “schools” of psychology. Later they invited Egon Brunswick to join me. He was at the time completely absorbed in working out a sophisticated conception of psychology *vom Gegenstand her* (from object), and we could not agree about the content of the proposed monograph. He would naturally concentrate on his way of conceiving psychology, a way that admirably deepened the “logical behaviorism” of the Vienna Circle. Nevertheless it was too narrow for the ency-

cllopedia, I suggested. We were close friends, however. I have never laughed so much with a basically suicidal personality. Our only conflict arose when I insisted on living outdoors in sleeping bags with my wife just above the Berkeley campus where he was professor. "A foreign scholar *cannot* live in the bush!" We were civilized, I explained, and we went down to the campus each morning to take showers. *No*, we had to rent a house. Unfortunately, Egon had problems with his nerves and had a central European acoustic sensitivity. He had to rest from about 2 P.M. to 4 P.M., but there were certain noises in the long corridor of the Psychology Department that he simply could not stand. He would rush to the door of his office and shout "MUST you whizzle Bach!"

These are perhaps details that are unnecessary to mention? I think not, because we who are admirers of the Vienna Circle of the 1930s and the logical empiricists should more often remember that there was a prominent, internationally acclaimed psychologist—and lovable personality—who felt closely related to logical empiricism, and who developed a system that immensely improved its "logical" behaviorism.

My *Erkenntnis und wissenschaftliches Verhalten* could also be used by logical empiricists, but it was more "speculative" and also basically empirical, not logical. The thesis of this work was that every scientific content of knowledge can be described in terms of behaviors (intentionality being inherent in *Verhaltensweisen* as conceived by E. C. Tolman, Egon Brunswick, and myself). However, such a behavior model of scientific knowledge is only one model; there might be indefinitely many other models with, in principle, the same level of adequacy. The "subjectivist" model cannot do the job alone because it does not transcend the behavior-consciousness dualism. The contents of knowledge cannot be adequately described in terms of states of consciousness. *Erkenntnisinhalt* cannot be separated from *Wissenschaftlicher Tätigkeit*. Each *Verhaltensweise* presents a synthesis, and internally relates the two inseparable aspects. Spinoza again!

It was a pity that I met neither Hans Reichenbach nor Edgar Zilsel, about whom I had heard so much. What I could understand of Reichenbach's philosophy of science appealed to me. One of the most enlightening opinions I construed him to have, I thought I could formulate as follows:

EMPIRICISM, POSSIBILISM, AND PLURALISM

Of course, creative scientists need mythology as do all creative people, and therefore also they need metaphysics, but the use is heuristic. Where scientific results are obtained, the myth can and should be peeled off. The next generation will need different myths!

Ending my personal account, I wish to express my feelings of sympathy both for the logical empiricists as immigrants in the United States and for their new friends who did what they could to relieve their pain. Their capacity to adapt was undeniable, but it had its limits. The tragicomic story Egon Brunswick told me should not be forgotten. The eminent linguist Karl Bühler (who especially through his “Bühler girls” kept a healthy contact with logical empiricists) had big and small difficulties—he could not, according to Egon, always clearly hear the difference between *d* and *t*. This conversation ensued. *Egon*: “As a famous European scholar and teacher of language you *must* not say Kenducky, you must say Kentucky!” *Karl*: “But that is what I say! I say Kenducky.” *Egon*: “No, no! I mean yes, yes, you say Kenducky. Say Kentucky!” *Karl*: “But Egon, *Lieber*, I say . . .” and so on.

It is for Austria and for the rest of the world a good thing that the works of the logical empiricists are now studied with care and renewed interest. It is a special joy for us who knew them personally to see this happening.

The Glass Is on the Table

Fons Elders: Ladies and gentlemen, I would like to welcome you to a debate that will, I suppose, be of interest in many respects. I would like to lose as little time as possible in beginning this philosophical contest, in which you will see an avid football fan, Sir Alfred, and a lover of boxing and alpinism, Arne Naess, debating with each other on central issues of their own philosophies. First of all, we have to discover what kinds of philosophical views both philosophers have. Sir Alfred and Mr. Naess, would you each explain to the audience what you consider to be your tasks as philosophers? Sir Alfred?

Sir Alfred Ayer: Well, I suppose to try to answer a certain quite specific range of questions that are classified as philosophical questions—and are very much the same questions that, I think, have been asked since the Greeks, mainly about what can be known, how it can be known, what kind of things there are, how they relate to one another.

In general, I would think of philosophy as an activity of questioning accepted beliefs, trying to find criteria and to evaluate these criteria; trying to unearth the assumptions behind thinking—scientific thinking and ordinary thinking—and then trying to see if they are valid. In practice, this generally comes down to answering fairly concrete specific questions.

And I hope, in a sense, to finding the truth.

This article was reprinted with permission from *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), 11–68. The debate, between Arne Naess and Sir Alfred Ayer and moderated by Fons Elders, was broadcast by the Dutch Television Foundation in 1971.

Elders: And you, Mr. Naess?

Arne Naess: Well, I see it a little differently, I think, because I would rather say that to philosophy belong the most profound, the deepest, the most fundamental problems. They will change very little, and they have not changed much over the last 2,000 years. So we have different conceptions of philosophy, but we agree that the epistemological question, "What can we know?" and the ontological one, "What main kinds of things are there?" belong to philosophy. As I see it, they are among the most profound questions we can ask.

Ayer: Yes, but how do you measure the profundity of a problem? I mean, a problem may often look quite trivial and then turn out to be profound. In a sense, you try to answer what you're puzzled by. Now this may be something very profound; it may even look quite superficial, then turn out to be profound.

Naess: How do we measure? Well, that's one of the most profound questions of all. How do we know? I suppose it will vary with cultural and social circumstances. It involves fundamental valuations, not only investigations of fact or logic.

Elders: Sir Alfred, would you give an outline of a sceptic?

Ayer: Well, I was going to talk about this. It seems to me that, perhaps, not so much in ancient philosophy, but certainly in modern philosophy since Descartes, a lot of problems have arisen out of a certain very characteristic sceptical argument. I should say that a sceptic is always someone who questions one's right to make certain assumptions—often assumptions about the existence of certain kinds of things—on the ground of their going beyond the evidence.

I mean, a very obvious and classical example would be scepticism about other minds. People will say, Well, all you observe is other people's behavior; all you observe is their actions, the expressions on their faces. How do you know that anything goes on behind? How do you know that everybody

isn't a robot, or whatever? And so you get scepticism also tied up with a certain neurosis, I think. It has also a certain emotional tone.

Or again take the classical example of the scepticism of David Hume, the scepticism about induction. Hitherto, when you lit a cigarette, it would smoke, and so on; when you have walked on the floor it has supported you. How do you know that this will happen in the future? How can you extrapolate from past evidence to future occurrences? And then you are proving that the argument is, in a sense, circular, always presupposing something that you can't justify. And a lot of philosophy comes out as the posing of arguments of this kind and the attempts to find replies to them. And you could even characterize different sorts of philosophy by their different ways of meeting the sceptic. Now, I think one mark of a philosopher, why I think that Arne Naess is a profound philosopher, is to take scepticism seriously. Would you?

Elders: But in *The Problem of Knowledge* you are quite critical about scepticism.

Ayer: I think I rather cheated in *The Problem of Knowledge*. It seems to me that I gave scepticism a good run, and then in the end somehow some little strong John Bull common sense came out in me and I took away from the sceptic the victory he had won, like a referee in a boxing match.

Naess: I had the same impression when I read your book. Ultimately you would say, "Hm, no! Common sense, after all, tells me there is something rotten here, so there is something rotten." But . . . well, I don't know your mind.

Elders: Speaking about this common sense, Sir Alfred, has it something in common with what the Germans call *Gesundenes Volksempfinden*?

Ayer: I don't know whether it has or not, because I don't know really which Germans you are talking of, or what they mean by this.

Elders: But what do *you* mean by common sense?

Ayer: By common sense I mean what Hume calls natural belief. For instance, take the case of the past. Now, in fact, you can't justify any belief about the past, because any attempt to justify it will be circular. The most you can do is check one memory by another one, one memory report by another one; or check in the records, and this again presupposes the reliability of memory, because how do you test the records? So you really have no non-circular justification.

So it's perfectly true to say, as Russell said, that for all we can *prove*, for all we can demonstrate, the world might have begun five minutes ago, with people already fully grown who delusively remember a totally unreal past.

Now I suppose, Naess, you want to leave it there and say: I really don't know. But I'd say, Well, the argument for it may be circular, nevertheless I'm going to assume it. This will be what I would call common sense. At a certain point I say, No, no, no, this is carrying scepticism too far: to hell with it.

And possibly that is a remarkable weakness in a philosopher: I should be more heroic. I mean, are you more heroic, more heroic in this way? Would *you* say we have no reason to believe that the world has existed for more than five minutes?

Naess: I think it is reasonable to say that it has existed for a very long time, and that it is reasonable that we should assume this. But that still leaves open the question of truth. Reasonableness does not rule out mistakes. Our concept of known truth is such that you must have a guarantee. But are we ever justified in saying that our research is over, we need not bother to test our beliefs any more, 50,000 years ago there were people living on this earth? We do not have any guarantees—or do we? I have not found any. The more I think about this, the less I come to feel that I know. That's a feeling you don't have every time you take a tram or walk on the floor. But in the moments when, as Heidegger would say, you live more authentically, that's to say you . . .

Ayer: Let's keep him out of this. [*Laughter.*]

Naess: I knew it, I knew it, and therefore I had my small pleasure!

Ayer: We ought to maintain certain standards.

Naess: Well, a man whose name begins with *H* and ends with *r* thinks, and other philosophers also, that we are more or less concentrated and integrated. In moments of high concentration and integration, not at the times when I am merely functioning, I have this feeling—and it is not just a feeling—that we don't have any decisive arguments for any conclusions whatsoever. That is, when the conclusion starts with "It is true that. . . ."

Ayer: And yet there is something peculiar here, in the way I view it, because we have got all the evidence. It's not like a paleontologist who might be doubtful about dating some fossils because, perhaps, more evidence will come in; perhaps someday more archaeological work will show him in which way his dating is wrong. But with sceptical questions, in a sense there literally isn't any more evidence to come in. No experiment could be made that would show us, one way or the other, that we *were* justified in assuming the existence of other minds. No psychoanalyst is going to still our doubts on questions of this kind. They are in a sense logical doubts; in a sense all the evidence is there.

Naess: There are so many conceptions of logic and of intelligibility, and of what an argument is, and of what is evidence. I feel that in questions of conceptual analysis you can never say, Now we have all the evidence here, now the cake is complete. Who knows the baker? Even in logical questions our situation resembles that of the paleontologist; we do not have all the evidence about the evidence. I am also against the idea that the collecting of evidence should always be a kind of collecting of the results of external experiments. Experiments should also be made with our logic and ourselves. What does the I, the ego mean? We use the distinction between the I and the rest—what does it mean? Philosophers have many, but doubtful, solutions, and I will probably go on trying to collect evidence until I die.

The mysteries that we "know" include those of "I," "know," and the link between the knower and the known.

Ayer: Yes, I'm not dissenting from what you say, I'm merely trying to get at what's behind what you're saying. Do you think we might discover any quite different criteria even of validity; I mean that we might suddenly say,

No, we don't want to use this logic? That you envisage even finding a different form of logic?

Naess: Yes, I expect the future here will resemble the past: continued modification of the conceptions of inference, criteria, and evidence. I don't think that in the year 2000 we will have a completely different conception of what constitutes evidence. But sometimes you add or subtract some kinds of evidence; and in a most unexpected way. As, for example, the concepts of proof in mathematics.

Ayer: Indeed, indeed.

Elders: Mr. Naess, I think we're still speaking a little evasively, because we can also formulate the problem of the past and the present in our own terms. Perhaps Sir Alfred will tell us how certain, how convinced he is that we are here now; and perhaps you could also speak on this question.

Ayer: Yes, I would say, if I were in a law court, I was convinced beyond reasonable doubt. [*Laughter.*] I wouldn't say it's certain; it's certainly logically conceivable that I should wake up and find myself back in my bed in London; that I've dreamt the whole thing. Although, of course, *that* experience might be the dream one. In that case, however, the question would be how things went on from then. But I would be convinced beyond reasonable doubt. I would bet on it. I would bet at least as much as you're paying me, for instance. [*Laughter.*] And I think Naess would too; he's more sceptical than I am, but he will keep a bet.

Naess: A little less willingly than you, I feel.

Ayer: But of course it's not simply a question of the fact of our being here; it's also how you are going to interpret that fact. We say we are here; but what are *we*? I mean, are these just bodies or do they have minds too? What's meant by their having minds? Are we going to regard them just as little bits of atoms, or are we going to regard them in a commonsense way as being consciousness looking outward? All these questions come up.

Just saying "We're all here" represents, I think, something that you are

pretty confident of. How, then, are you going to analyze that? What ontology do you envisage? This is again disputable.

Naess: You are now speaking as a sceptic here, Sir Alfred. We don't disagree on a single point here. But an important thing in scepticism is this: that anything can happen somehow, and that perhaps all things are somehow interconnected. Perhaps no question can be solved in isolation.

The question "Is this a glass?" is somehow irrelevant in relation to the basic problem that all things are interconnected. The particular question "Is this a glass?" evades the fact that there are several different ways of looking at the glass, that there are different relationships between human beings and a thing, and that all these interconnect.

Elders: But you still presuppose the entity of the glass.

Naess: If you say "presuppose" an "entity," that raises a tremendously difficult question. Do I ever presuppose?

Ayer: Well, of course, an enormous number of presuppositions are built even into the language we are using. If we talk about our being here at all, it presupposes first of all an assumption of human beings in some sense or other, a whole spatio-temporal system, the glass you're looking at, even the very terms we're talking in. But I wanted in fact to ask you, How serious is your scepticism? You say anything can happen. Now I perfectly agree that it is logically possible; there is no contradiction, no formal contradiction, in the idea of all these people turning into swans, and even Jupiter coming—I think Jupiter is going too far, but some human analogue of Jupiter coming in—and behaving as he did to swans. This is logically possible, but you don't envisage it as a serious possibility.

Elders: As an empirical possibility.

Ayer: I mean, it seems to me that although one admits the logical possibility, one doesn't think it will happen. One's scepticism in actual life, in one's actual beliefs, in the way one plans one's life, is pretty narrow because of the extreme force of what Hume called natural belief.

We are conditioned to make certain assumptions, to take for granted that things *do* go in regular patterns. A really serious scepticism might be represented by someone who really would refrain from taking action because, after all, the man that I shake hands with *might* suddenly explode; therefore, he says, I won't go near him. This is, if you like, an armchair scepticism, but I would not for this reason say that it was not serious, for I think that purely intellectual problems are serious. But it is, in this sense, theoretical.

Elders: You agree with this sharp distinction between logical and empirical possibility?

Naess: Well, this is not as important as certain other things that were said at the time, if you will excuse me.

I would say that sometimes I'm just functioning. When I buy a ticket to Groningen I neither assert anything nor deny anything; therefore I do not presuppose anything. I just walk, talk, and go. I don't quite feel a philosopher at such moments. I do not assert the truth or falsity of any proposition: I just function. I act with a certain *trust*. A trusting attitude in walking and buying things for paper money. I think it's a trust toward things, not propositions. And that's different from making an assertion; this *is* true and the other *is* false. That's one point.

The second point is this, that I could easily imagine that a certain lady here in the room might become a swan at any moment. I also tend to think something completely different—so many different, incompatible things, that they must collide with each other.

Therefore I'm not afraid that we shall explode, for if anything and everything can happen, you're no longer afraid. You may explode but it may not hurt you. If you only think something dangerous will happen, you're afraid; but if anything can happen, you simply calm down. And that's how I feel.

Elders: So as a sceptic you are less afraid than Sir Alfred?

Ayer: I think that if I thought anything could happen I should be afraid, yes. Anything whatsoever.

Naess: Well, that may be because you have had some bad experiences, but I have mainly had good experiences.

Ayer: No—I think it's just because I have a more feverish imagination.

Naess: Basically I have had good experiences with other people.

Ayer: But in *this*, you see, you're now doing exactly what you ought not to be doing: you're generalizing from past experiences. You say you've had good experiences, therefore you expect only good things to happen. But this is not just allowing anything to happen, it's allowing only what has happened to you to happen.

Naess: That's a misconception of scepticism.

Ayer: It's in your natural belief.

Naess: This is a first-semester scepticism. Not generalizing and using a lot of "perhaphses." In the second semester you utter generalizations because you do not strongly resist your own tendency to utter what strikes you. As I say something about all people and I don't believe it to be a truth in the sense that I'm convinced it is true in the moment I say it. But if you say, Oh, Mr. Naess, you are generalizing and speaking about all good experiences with all people, then I would say, Yes, yes; I generalize quite naturally, but I couldn't give a good argument for the truth of what I am saying.

So, generalizing is okay for a sceptic; if he is relaxed as a sceptic he will make a lot of generalizations, but *without taking them too seriously*. [*Laughter.*]

Ayer: Yes, I mean, every moment it's true; of course, you're taking generalizations seriously now in reaching forward confidently and drinking your orange juice. You're taking generalizations seriously because a huge amount of theory goes into this—theories about the behavior of the glass, about the liquid that's in the glass, about your own body, about the behavior of your neighbors, deciding that they will not suddenly go mad and start to be violent, all sorts of theories. Every minute, you're making an enormous number of assumptions of this kind.

Naess: But do I assume the truth of any proposition? Scepticism has to do with claims about the truth. During the war and during the Hitler regime, and when I meet people who are really convinced that what Marx says is true, then I feel the importance of a sceptical attitude; these people take the attitude that what they're saying just couldn't be false, an attitude of unshakability and incorrigibility. This I fight. I can be shaken and I wish others to be able to be shaken! The stand against incorrigibility somehow becomes generalized until it colors one's total view. But I think one of the roots of unshakability and incorrigibility must lie in political and social conflicts.

Elders: Well, will you try to apply what you are saying now to the concept of democracy?

Ayer: That's a big jump!

Naess: Well, I have for instance discussed and published more than 300 different definitions of democracy, in order to undermine politicians who say that democracy requires such and such—Soviet theorists who say that *they* breed “real” democracy; and British democratic politicians who say that “real” democracy is very different. But I only undermine, not accuse of error. The British traditions go back to certain authors in the Greek world, and the Soviet conceptions go back to Plato and Aristotle. So they all have a “big shot” behind them. What I do is merely to make it complicated for propagandists to monopolize the term.

Ayer: Ah, something I was interested in: you used the phrase “*real*” *democracy* and I think this brings out an interesting, indeed philosophical point, namely what Stevenson called persuasive definitions. When you say real democracy, the word *real* here is, as it were, an okay word, it's trying to capture assent for your conception of democracy. Not essence, I'm not saying that I mean there is no essence of democracy; the word *democracy* means what we choose it to mean.

And you're therefore trying to capture assent for a certain definition of the word, and of course not simply assent for a certain use of language, but trying to gain adherence to a type of behavior that is associated with the lan-

guage. Someone might say, Well, real democracy consists not in the right to vote, but in economic equality, shall we say. What he's then doing is trying to capture the favorable word *democracy* for a policy that he advocates. And I think that with questions like how you define democracy, what they're really asking is not in the least how you define the word; they're not asking questions of lexicography, they're asking you for some kind of political program, the word *democracy* now being one that has got favorable sentiments attached to it. And presumably you arranged your 300 definitions in some order of desirability. I mean, there were some you wanted to be accepted more than others, that even reflected your own political opinions, presumably.

Naess: Sure, to do that is very tempting. So far, I have only undermined the use of the slogan "democratic." But, I'm sorry to say, in some ways I feel miserable to be defending scepticism now, because there is a very tragic conflict between the attitude I hold in my integrated and concentrated moments, which is more or less sceptical, and the requirements of consistent action. For instance, when we believe that we really must do something about some terribly pressing problem, we must somehow narrow down our perspective. The vast plurality of possible worlds—and how do we know in which world we live—are suddenly not only irrelevant, but contemplation of them undermines the willingness and capacity to act. Most people are only willing to act forcefully and consistently when they have a belief in *the* truth and close their minds to all else.

Ayer: But I should have thought this was a field in which a certain kind of scepticism anyhow was very desirable and fruitful. It's very healthy indeed not to listen to the rhetoric about democracy, but to look at the facts. Look and see what actually happens: see how people live their lives, see what is actually done in the law courts, look behind the words to realities. This is in a sense a formal scepticism, although you're not sceptical about the words that we use to mark them with. And I would think there that your approach is thoroughly sceptical and at the same time constructive in this field.

Naess: Yes, it's desirable that people should be like you in this way, but mostly they seem not to be like that. The students say that we must get rid of particular textbooks of Naess because they undermine convictions and

will undermine collective action now and over the next five years. And this is real; it is a tragedy, because they need rhetoric and dogmatism, I think. Scepticism breeds passivity. I do not feel that way, but the students do.

Elders: But, Sir Alfred, if you are stressing this point of the relationship between certain philosophical schools on one hand and certain values on the other hand, do you see any relation between your empiricism and your role as director of the Humanist Movement in Great Britain?

Ayer: Yes, I see some relation. I don't see a relation in the sense that I would be able to deduce my political or my social views from any set of metaphysical or epistemological principles. I don't think that, in this sense, I have a coherent system or that there can be one. But of course, I think that there is some relation, inasmuch that if one has an empirical, even sceptical temper of mind, then one will be hostile to rhetoric, or at least one will look for the facts behind the rhetoric.

I've been a humanist, for example, partly because I could see no reason to believe in the existence of God. And therefore I would be opposed to people who not only maintained this, but also based political or social programs on it.

I would be a humanist inasmuch as I think I would be professionally opposed to humbug of any kind: the kind of humbug that you too often find in people in power, in judges and people of that sort. And, in a sense, I would expect an empirical philosopher to be radical, although if one looks at history, this isn't always so. Hume, who was the greatest of all empiricists, was in fact, if anything, a Tory. This was partly because of his scepticism. He was so sceptical about schemes of human improvement.

Elders: Like Schopenhauer.

Ayer: Yes. But in general it has certainly been true in the last century or so that there has been a close association, so close an association between empiricism and radicalism that it couldn't entirely be an accident. But I think it's a matter of a certain habit of mind, a certain critical temper in the examination of political and social as well as philosophical questions, that is responsible for this, rather than some deduction from first principles.

Elders: Yes, but these are not really arguments, but merely a piece of history.

Ayer: I'm giving you an explanation. You asked me what I thought the connection was, and I . . .

Elders: The historical explanation. But we're talking now on the level of arguments about the relation between empiricism and humanism.

Ayer: But it's slightly more than this, because I think a certain habit of mind, a certain critical temper that you would develop if you did philosophy in the sort of way that Naess and I do it, would on the whole tend . . . after all, you bring the same intelligence to bear on any of a wide range of problems, even though they aren't necessarily the same problems, and this would, I think, tend to have the effect of making you a liberal radical in social and political questions. This would be more than just a historical accident, as it might be if I happened to be both Protestant and have brown eyes; it's not as accidental as that. There is, I think, some causal connection of a very close kind.

But I don't think that I can, from any kind of empiricist premises, deduce a political program. I mean, you can't get rabbits out of hats that don't contain them. Do you agree?

Naess: Well, no! First of all, you expect that as philosophers we should somehow be able to deduce them, whereas I would say our responsibility is to connect our views—our ethical and epistemological as well as our political views—in a fairly decent way so that we get a coherent whole. The connections may be looser than ordinary scientific connections, looser than deductions. I think we disagree here on how we conceive of our roles as philosophers. I consider myself a philosopher when I'm trying to convince people of nonviolence, consistent nonviolence whatever happens. That is a fairly fantastic doctrine, considered descriptively or empirically. I must therefore make clear, to myself and others, what kind of normative principles I also make use of, and derive from them the special norms and hypotheses characteristic of a Gandhian strategy of conflict behavior. I think I believe in the ultimate unity of all living beings. This is a very vague and ambiguous phrase but I have to rely on it. It is a task for analyti-

cal philosophy to suggest more precise formulations. Because I have such principles, I also have a program of action, the main outline of which is part of my philosophy. So I might suddenly try to win you over to consistent nonviolence and to persuade you to join some kind of movement—and this in spite of my not believing that I possess any guarantee that I have found any truths.

Ayer: I can see you might indeed try to persuade me of this, but I don't think you'd persuade me of these methods. The ultimate unity of living things: I mean . . .

Elders: Is this metaphysics, in your opinion?

Ayer: Well, it could be an ordinary scientific statement. In fact, it would include not only living things but also inanimate things, if they are all made of atoms; in this sense they are homogeneous. Then I suppose there is more homogeneity between organic things, although the difference between organic and inorganic is so slight.

It doesn't seem to me that on any scientific basis of this sort, one is going to build an ethical view. After all, civil wars take place, and the people who fight each other in them don't deny that they're each human beings and even belong to the same nation: but it doesn't stop the fighting.

So, in fact, this alone is not going to be sufficient. You have to put up some moral principle, which is not going to be deducible from any factual or metaphysical one; that it is wrong to take life of any kind. But do you then extend this to all life, mosquitoes and the like, or just human life? I'm not saying this ironically: I think that it's a perfectly defensible position to be vegetarian and so on—I'm not, but I think . . .

Elders: But will you try, Mr. Naess, to give the metaphysical foundation for your belief in nonviolence, about which we can speak later? We are still at the level of principles and arguments for or against metaphysics.

Ayer: And it's partly political too, isn't it? It's not just metaphysical. How well Gandhi did against the British; he would have done less well against the Nazis.

Naess: Yes, metaphysical and political and anthropological, all at once, all in one: therefore systems are unavoidable. Gandhi as a leader in Germany? Perhaps one million Jews killed before 1938, none after. He advised resistance, not submission. The metaphysical principle here of course belongs more to the Indian than to the European tradition.

Ayer: Yes, I would say so.

Naess: But the ecological movement may change the European tradition. The formulation “All living beings are ultimately one” is neither a norm nor a description. The distinction between descriptions and norms and even imperatives can be put in afterward, semantically speaking. It is the kind of utterance you make in support of something I would call an intuition, by which I do not mean that it is necessarily true. In moments of concentration you are aware of vast perspectives: yes, that is the thing, ultimately life is one!

And then you start to ask yourself how you can argue for this and what does it mean; and at this moment you need a norm, a system of ethics and an ontology and plenty of hypotheses in many fields covered by the sciences. And you say, A mosquito and myself are obviously not biologically the same, so I must mean something different from it. For instance, something like: if I hurt you, I hurt myself. My self is not my ego, but something capable of immense development. Think of a picture from the war: a young man is just going to throw a grenade and there is another young man, the so-called enemy, very similar to him, also intending to do the same at exactly the same moment. It’s a case of “him or me”; but they are also obviously aware of the fact that they are the same kind of being and that to throw grenades at each other is really nonsense. They are one.

Ayer: Well, I share your moral sentiments, but I think what you’ve been saying is very largely just false. It’s like the schoolmaster who is going to beat the boy and says, This is going to hurt me more than it’ll hurt you. That’s an absolute lie; it isn’t going to hurt the schoolmaster at all—on the contrary, in only too many cases it’s going to give him pleasure.

Naess: The boy also, if he’s a masochist.

EMPIRICISM, POSSIBILISM, AND PLURALISM

Ayer: The boy also if he's a masochist, yes. But, in fact, what you are saying simply isn't true. I mean, not only I and a mosquito, but even you and I are not one. Of course, if I sympathize with you and you are hurt I shall be sorry, but I shan't be hurt in the same way. It's indeed true, empirically true, that to a rather limited extent human beings sympathize with one another; with people they know and like, and people they feel in some way close to. But to say that they're one in any literal sense is just false. I'm not identical with you, and it would be a terrible thing if I were, in a way. [*Laughter.*] I mean, this discussion would be very difficult.

Elders: Or it would be much easier.

Ayer: Ah, well, yes, it would be. It would be even more solipsistic than it sometimes tends to become.

Elders: Growing more and more together.

Ayer: It seems to me that clearly, if one takes these things literally, they're false; and therefore you take them metaphorically. Now, it's just when you take them metaphorically that they become moral principles of a perfectly respectable kind: that you ought to treat other people as though they . . . I mean, if you like, as in the Christian way of thinking. . . . I mean, deal with other people as you wish them to deal with you. They wouldn't necessarily have the same tastes, but in a sense one should treat other people as if they were as important to you as yourself. This is a perfectly good moral principle. But why pretend that we are identical when we are not?

Elders: Now you need some whiskey, Mr. Naess?

Naess: No, no. You are too rash.

Ayer: He doesn't want to identify with me too much, does he?

Naess: Too rash, you are too rash. First of all, there is no definite literal sense of an utterance like this in relation to its metaphorical sense. You have to analyze it from a great many points of view. Its so-called literal meaning is

hardly exemplified in any available text; what is the literal sense of the identity of all living beings?

Ayer: Well, I mean it in the sense in which the *Evening Star* is identical with the *Morning Star*; in the sense in which the Young Pretender is identical with Charles Edward Stuart; in the sense in which the author of *Pickwick* is identical with the author of *Oliver Twist*: this is what I would call the literal sense of identity. Now it's up to you, since you're not using it in that sense, to define a sense in which you are using it.

Naess: That's right.

Ayer: And now I subside.

Naess: Good. That's better. [*Laughter.*] Have patience!

When we say that we are the same, three concepts may profitably be interconnected. The ego, the self with a small *s*, and then this great Self, with a capital *S*, the *ātman*, which you hear so much about in Indian philosophy, but also, of course, in certain Western traditions. If you as a boy had had a very much wider development, your self, what you take to be part of you, would not only include your body, it would include everything that's yours, so to speak; so what is yours would have been much wider.

This justifies the tentative introduction of an entity, the Self, with a capital *S*, the power of which gradually increases. You might still say your limits are those of your body, but there you would have to include units of your central nervous system such as, for instance, those corresponding to the Milky Way and the Andromeda nebula insofar as you have sensuous or other bodily interactions with them.

And in this kind of philosophy they ultimately believe that human beings can develop in such a way, that in a sense their selves include the other selves in a certain way.

Ayer: But in *what* sense? In *what* sense does my self include Fons? Or could it ever, however much I thought of him?

EMPIRICISM, POSSIBILISM, AND PLURALISM

Naess: Now you are too impolite. Fons is not utterly different.

Elders: I should like that.

Ayer: I'm sorry, but I don't know, I . . . Fons would like it.

Naess: Philosophy is just this; that you develop something that I've started and gradually you introduce preciseness from different directions. Then you breathe three times, reinforce your intuition, and go a little further toward precision. But there is no hurry, this process will take a long time. And of course sometimes intuitions vanish for some of us; for instance, those of "absolute movement" or of an absolute "voice of conscience."

I suppose you would say that the limits of the self gradually increase from infancy to puberty; and the sense in which it increases is, I would say, what you are concerned about. What you identify yourself with . . . the norms you internalize.

Ayer: Ah! Now that's, yes . . .

Naess: And concern in the sense in which you say *my*! You use the possessive term, my—*my* mother, for instance.

Elders: I think in a biological sense we form a chain of divisions; so for example, in this sense, you can use the meaning of the greater Self, against the small self or ego.

Naess: Yes, biologically we are just centers of interactions in one great field.

Ayer: But why put things in a portentous way when they can be put in a simple way? Why not say that as you grow older you come to comprehend more things; your knowledge perhaps increases, and then after a certain point, I'm afraid, diminishes again. But up to a point it increases. Perhaps your range of sympathy is greater: perhaps you identify with more things and sometimes again with less.

Again, one can't always generalize; some people differ in this respect, some people narrow themselves in the sense of concentrating more on

themselves. When one has a fairly precise method, a precise way of describing all these facts, why does one have to make such portentous statements about one's self expanding and including everything. It sounds romantic, but it's quite superfluous when what you mean can be put quite definitely: that these things happen, and these things are empirically testable. I would say that what you're describing is true of some people, not of others.

Naess: Well, what is portentous depends on at which university you are studying.

Ayer: Portentous. I did not say pretentious, that would have been rude, I said portentous.

Naess: I meant portentous also: and that depends on the university. If you had been at Oxford or Cambridge at the time of Wittgenstein, it would have been a different thing than what it was at the time of Bradley and of the Hegelians. Trivialism is portentous if carried to extremes. But let us go back to the belief in the pervasiveness of the "I." Well, people then used certain terms about which we now would say, Oh, my God, don't be so portentous. So this is completely relative, I think. There are a million things to be said: must they all begin with "I"? Spinoza introduces the "I" in part two, not in part one, of his system. Do we have a definite ego all the time? Isn't that a weird construction? A Cartesian prejudice? "I developed from this to that" or "Now I am developing more in this direction" or "I was very different when I was thirteen from when I was twelve," and so on—I, I, I!

Must we think that there is such an entity? I wouldn't simply think there is a definite entity there. Without this scepticism I would not feel "All living things are ultimately one" to be a good slogan.

Ayer: I don't think I disagree with you there. I certainly don't want to postulate any sort of Cartesian substance, anything of which the ego could be a name. I'm very puzzled about this, I don't at all know the answer to it, but I'm inclined to think that you can't find a personal identity except in terms of the identity of the body.

But of course, if that's right, if you can only define personal identity in terms of bodily identity, then your thesis that one's identity could include

other people would become false, except if some kind of bodily identification were to take place. I'm not very positive about this, but let us take, say, the relation between you and me. We're about the same age, your self and my self are sitting here now, and two small boys went to school so many years ago. Now clearly there is a physical relation, in the sense that there is a spatio-temporal continuity between these bodies and those ones, and there are also certain causal connections. I mean that what we are thinking now is causally dependent upon what happened to those bodies then. Whether there is more than this I would be inclined to dispute—except for memory, but that again could be held to be a function of physical stimuli.

So I'm inclined, I think, to equate personal identity with bodily identity, but I'm not sure about this.

But even if this equation were shown to be wrong, as it easily might be, I wouldn't want a Cartesian substance. I would want something like a Humean theory of a series of experiences linked by memory and the overlapping of consciousness and so on, so that in this sense I don't want to attach too much importance to the I.

But I think I wanted to say that in whatever way you define the series of experiences that are properly called mine, they are always exclusive of those properly called yours. I don't think that series of experiences from different persons can logically intersect. Although paranormal psychology might produce phenomena that one might want to describe in this sort of way. I don't want to be at all dogmatic about this.

Naess: I'm genuinely glad to hear this. I agree concerning the term *experience*. Its logic is subjective: insisting on using that term, you are caught in the same trap as Hume.

Perhaps before the year 3000 there will be "hardware" people, let us say people who have abandoned their brains, taking in computers instead. Collectivists may prefer this: it might herald the end of egos. But it couldn't be quite the end, and is perhaps not central to what we are speaking about. More central is the fact that, as a philosopher, I think I have a kind of total view, which would include logic, epistemology, and ontology, but also evaluations, and that I do not escape from the relevance of them at any moment. When I'm saying who I am, so to speak, I cannot avoid indicating what kind of evaluations I make, what kind of priorities or values I have, et

cetera. And there it seems to me that we get into a metaphysical area, a “portentous” area, because only there do we realize just how many different conceptions of fact and experience are possible.

I have a feeling that the empiricism that I suspect you are inclined to accept is too narrow, in a sense that you do not admit a commitment to statements that are untestable empirically. I am inclined to say, Your thinking is too narrow. Would this hurt you slightly? If I hurt you I hurt myself, which means that if, for instance, I now said something to you and the next moment I thought that it had been unfair of me to say that when I realized that it had hurt you somehow—not that you couldn’t easily win an argument—but if it had hurt you, I would have a moment of identification. Phenomenologically there would be “one” hurt, which was not yet “my” experience. I expect you now to jump into psychology and say that when you identify yourself with somebody else this is a matter of psychology, not philosophy, and that we have the empirical evidence from more or less good experiments that can show us to what extent we identify with each other. It has no ontological consequences. If *A* identifies with *B*, he remains *A*.

But for me it is more a question of what in German they would call *Einstellung*; it’s something that is not reducible to empirical psychology, because whatever the psychologists find, I would stick to it probably. They are committed to a definite conceptual framework from the very beginning.

Ayer: Yes, I wasn’t going to take that move, because I don’t think these labels matter all that much: these are classifications for librarians. I think we should be free to say what we like in every field if we like. I was rather going to take up what you said earlier about this question of who I am. I think when I was arguing before I was using it more in what could be called a “passport” sense; for example, who is Arne Naess? I would say that he is someone who answers to such and such a description, whereas you were clearly using it in a wider sense than this. You were meaning by “who am I?” something that has to do with your own conception of yourself. When you said that hurting me would hurt you, this means that it would in some way be injurious not to your identity as the passport Arne Naess, but injurious to your conception of yourself, injurious to the sort of man you like to think of yourself as being. And possibly also if you hurt me it would have repercussions on your own character, and therefore in this sense you’ve in-

jured yourself. You wouldn't literally feel the pain that I felt, but you would be damaging yourself; which means that you are, in a certain sense, identifying with me, because you regard it as part of your conception of yourself that you don't gratuitously or voluntarily or deliberately hurt other human beings.

Now there seems to be no quarrel here whatsoever. But I think that if there is a difference between us, it is that I make a sharper distinction than you do between what's descriptive and what's normative. I would say that this was simply an announcement of what rightly, to put it in this way, could be called a policy.

I mean, it is perhaps not quite right, it's somehow not so deliberate as that, and it's more important to you than that. But this is a form of life that you're adopting, and something that goes very deep, and you put this forward, if you like, for me either to imitate you or disagree with you.

But, I think that a mistake could only arise, and I should only have a quarrel with you if you tried to prove it by deducing it from what masqueraded as a statement of fact. If you accept what I have just said as what you mean by "you and I are one" or "you identify with me," then we are talking in sympathy. It's only if you say that you have this policy *because*, and then make this appear as a factual statement, that we then quarrel on intellectual grounds.

Elders: So, in fact, the central question is the relationship between metaphysics and morality.

Naess: A norm or a moral injunction should not masquerade as a description; but neither should a statement involving description, for instance factual description, masquerade as a norm. "All living beings are ultimately one" admits partial interpretations or analyses in various directions, descriptive and normative. None seems to be exhaustive, which is typical of good old metaphysical formulas.

Incidentally, the distinction between fact and norm, or injunction, is ultimate: it is not that I think the norms are less normative, but that the descriptions are less descriptive. Description presupposes, for instance, a methodology of description. A methodology includes at least one postulate, at least one rule. A change of postulates and rules changes the descrip-

tion. This makes the notion of description as opposed to norm a little shaky: therefore I no longer use the term *fact*. It suggests independence of postulates and rules.

Elders: There we go, Sir Alfred.

Naess: I am sorry, I would feel badly if you were to take me as just a Heideggerian or some kind of . . .

Ayer: No, no, on the contrary, I mean, I wouldn't . . .

Naess: I'm not so sure I'm not. I'm quite near Heidegger in a certain sense.

Ayer: Nonsense, nonsense, nonsense!

Naess: Yes, we are *Geworfen*. I feel very much that I have been thrown into the world, and that I am still being thrown.

Ayer: Now *why* do yourself this injustice? Why spoil it? Now leave him out, keep him out. How do you know we are thrown into existence? You may have had a very difficult birth for all you remember.

Naess: How do I know? How do I know the relevance here of knowledge?

Ayer: Thrown into existence, nonsense.

Naess: Perhaps you use the term *know* too often.

Ayer: This should be eliminated.

Naess: Let's get away from being thrown into existence. . . . Yes, I shall try to trust you when you say that I am not thrown!

Ayer: Okay, but I take your earlier point, which I think is an extremely important one, about the vulnerability of the notion of fact.

I think we need the notion of fact, because we do need a distinction be-

tween fact and theory at some level: we need some kind of distinction between the deliverances of observation and the explanation for them. But of course it is not a sharp distinction. And if you like to say that what we call facts are already theory-laden, I would say it is a fact that there were more than two glasses on this table, and I should agree that an enormous amount of theory has already gone into this.

And I would share your scepticism about anything that might be called pure unadulterated fact. I think probably that doesn't exist, that there is already some conceptualization here, and if you like, conceptualization is already to some extent normative; pragmatic considerations have already come in, in the way we classify things, since the classifications are based on what we find it useful to do. So I quite agree that the distinction isn't an absolute one. The only question is whether it's relatively strong enough to bear the sort of weight I want to put on it. And I'm again hesitant about this.

Naess: I'm glad you are hesitant. But of course, when you say we need a concept of fact, of hard fact, I say some need it sometimes. But who, and when? It's not the great Self, it is the small self that needs limitation: it is when I'm functioning in tough practical situations, but not when I'm deciding what it is worthwhile doing in life, when the very widest perspectives are involved and when one is concentrating and meditating.

Ayer: One needs to make certain distinctions in order to move forward a little bit. You must take certain things for granted in order to make a further step, and then possibly you go back and question other things; otherwise you never start.

Naess: Yes, I agree. But it doesn't help you when you're saying that we need a concept of fact, for example that this is a glass.

I do not think we need a concept of fact, and we do not even need a concept of knowledge, in what I would call fundamental philosophical discussion. After a lengthy discussion, when we really get down to subtleties and refinements and also fundamentals, the term *fact* no longer occurs in your speech; neither does the term *I know* occur in mine as far as I can see. But there is this kind of vanishing—somebody said that the state

would vanish, though they say it less and less now, I think—and I would talk about the vanishing distinction between description and norm, fact and nonfact: the vanishing distinction, not vanishing facts, but the vanishing distinction . . .

Ayer: Well, the vanishing distinction between truth and falsehood?

Elders: No, between fact and interpretation.

Ayer: Well, then I would say I would need the concept of fact to maintain the distinction between truth and falsehood, to maintain some notion of truth as stating what is so and falsehood as stating what is not so, and using *fact* as a purely general term to cover what is so.

Naess: But you don't need the term *fact* in order to maintain the very general distinction between true and false. . . .

Ayer: I don't need the actual term, but I need some term doing that work.

Naess: I don't think so.

Ayer: You don't admit it—you do?

Naess: Well, not in order to uphold the distinction between true and false. There is a need for the term *fact* in everyday trivialities, like when I pick up this glass and . . .

Elders: Well, but in a logical sense you don't need any fact. . . .

Ayer: No. You could certainly do without the actual term *fact*, because one can talk of propositions as being made true by states of affairs, by events, by things having certain properties, or whatever. But I still think you need something to stand for what stands on the right-hand side of the equation. You have an equation: such and such a statement is true if and only if . . . and then you assert whatever it is. For instance, "You and I are sitting here" is true if and only if you and I are sitting here. Then you want some generic

EMPIRICISM, POSSIBILISM, AND PLURALISM

term, it seems to me, to describe these states of affairs that in the last resort verify or falsify all the statements that we make.

I do want some residue of realism, I want something out there that in the last resort makes our statements acceptable or not acceptable: in the end one can't say that anything goes. It's all very well my wanting to believe that I have a thousand pounds, or a million pounds in the bank. I go to the bank and I try to draw it out and it's a fact that the cashier doesn't pay it to me.

And in the last resort one wants some, I don't mind what term you use, but some term, it seems to me, to characterize, in any philosophy, really this . . . the brutishness of things, the hard things you stub your toe against. Yes this, like Dr. Johnson. [*Strikes his fist on the table.*]

Naess: Excellent. But it is highly characteristic, I think, of your monumental tradition of empiricism in England, in Britain, I should rather say.

Ayer: England I prefer. I'm not a Scot.

Naess: I would say British: the Scots were wonderful empiricists. But when you need a term for something, if you say this: it snows, it does not snow; this is true if something, something . . .

Ayer: That's right, the actual stuff.

Naess: . . . then you get the idea: ha, facts. No, that is British, [*laughter*] that is not universal. The Bengali seem never to get the idea; think of Tagore and others. . . .

Ayer: If it were British, alas, we should be in a much more powerful position than we are. I'm afraid it's becoming American.

Naess: Well, I learnt from housewives and schoolgirls another way of putting it. They say that something is true *if* it *is* so. Marvelous. It is a little wider than "it *is* so," and much wider than "it *is* a fact." It's true *if* it *is* so, it's false *if* it *isn't* so. Marvelous. But very little is said, of course, concerning testability.

Ayer: But “its being so” is what I call a fact.

Naess: “*If it is so*”; we have a conditional there, and there we agree.

Ayer: Yes.

Naess: It is only true “*if it is so*.”

Ayer: Certainly.

Naess: But what *is*? What *is* there? And here we must be terribly comprehensive, if we are to include all living ontological traditions. And to narrow it down to facts is to narrow it down to the British Isles first of all.

Ayer: Oh no, no, no, you mean, only in the British Isles anything is so? I’d be very sorry to hear this.

Naess: No, on the contrary, “Anything is so that is so” is more, is broader than “What is a fact?” And the British tradition, which politically speaking is sometimes, I’m glad to say, very good in comparison with the opposite German attitude . . .

Elders: With the Labour government or with the Conservatives?

Naess: Both, they are identical as far as . . .

Elders: Do you agree, Sir Alfred?

Ayer: They’re much more similar than I care for.

Naess: Yes, and very British.

Ayer: No, when the last government was in power, I thought, These are no better than the Conservatives. But now that the Conservative government is in power, they are worse.

Naess: When you say “they are worse,” would you add, Well, I just talk like this, it is not part of my philosophy? Personally I would say, This is part or should be part of both our philosophies. “They are worse,” you should be able to say that . . .

Ayer: I do say that, constantly.

Naess: But you might do more than say it, you might take it as part of your personal philosophy, or your *total view*. And there we are—the total view—which is considered unclear, unempirical, metaphysical in a bad sense. Because if you have a total view, somehow it hangs together and you always see the facts only as structures within a great body of hypotheses.

Ayer: You can’t seriously maintain, can you, that every opinion that I hold, or every emotional preference that I have, must be tied up with my philosophy. For example, I’m a lifelong supporter of Tottenham Hotspur, a football team: it is absurd to say this is part of my philosophy and that, had I happened to support Arsenal instead of Spurs, I could not be the positivist pragmatist that I am, but some sort of absolute idealist.

This is being ludicrous. I have lots and lots of opinions about all sorts of things: political opinions, aesthetic opinions. If you like, they’re all unified in the sense that it’s the same person who holds them; and possibly some very clever psychologist could trace some connection, could realize that there was something in the Spurs type of play that would appeal to philosophers of my sort possibly more than something, shall we say, in the play of Manchester United. But why do we have to go so far? Why not leave me in my compartment?

Naess: No, not today. No, if you say “they are worse” and you think of a Labour government, or any other government, you do not mean worse as football players, you mean worse . . .

Ayer: I make a moral judgment, yes, certainly.

Naess: Partly moral, partly political and economic.

Ayer: Mainly moral.

Naess: And to me that means that you are already involved in philosophy. There are degrees of philosophical relevance. Not all moral judgments are part of your system, but all moral judgments of yours should hang together within the framework of your philosophy; let us distinguish frame and details. So every moral judgment you make is relevant to your philosophy without being part of it. The mythical fall of the apple that struck Newton is not described in a physical system, but it is a physically relevant fall.

Ayer: In this sense I don't think I have a philosophy.

Naess: I suspect you don't have.

Ayer: I don't think so, no. I don't think that anyone *should* have in this sense.

Naess: Should! Another ethical judgment.

Ayer: It seems to me that I have an intelligence such as it is that I . . .

Naess: Here is a moral issue for you. I shouldn't have such a philosophy—your general statement included me.

Ayer: I think it tends to confuse your thought. I think you'd be a better philosopher if you did not have such a philosophy.

But I don't know, it is such a silly question: are you speaking as a philosopher? What does it matter? Am I speaking as an Old Etonian, am I speaking as a former member of a regiment and so on. I mean, it's irrelevant. The question is, What are you saying and what are the grounds for it and how would you defend it? But this "are you speaking as a such and such?" seems to me to be somehow a red herring. I'm not speaking as a fisherman, I am not a fisherman in fact . . . not even of souls. [*Laughter.*] The point is to say, Well, all right, you hold these principles about the Conservatives; why do you think they're so bad? And then I would say something

EMPIRICISM, POSSIBILISM, AND PLURALISM

about the dislike of the kind of businessman's outlook they seem to represent, this "let me make as much money as I can" that is the true characteristic of many of them. This, in a sense, is the theme that runs through their policy and attitudes.

And then you say, Are you speaking as a philosopher? I don't know how to answer this if you mean, Do you deduce this from your views about the problem of perception? No, I don't. If you mean, Is this in any psychologically recognizable sense the same person as wrote those books?, yes, it is. What more do you want?

Naess: I wonder, if you said . . .

Ayer: Or was it already enough?

Naess: . . . you shouldn't have a total philosophy; you would be a better philosopher . . .

Ayer: I don't say "you should," I say you haven't got a total philosophy.

Naess: But you said "you should" . . .

Ayer: I also shouldn't have . . .

Naess: I do not forget it. You said I shouldn't have it.

Ayer: Yes, I will maintain that, I'll maintain "you should not." Liking you as much as I do, I change this to "you do not."

Naess: Too late!

Ayer: But I'm prepared to maintain also "you should not."

Naess: We probably agree that a dogmatic view of all things lacks value, even if it were possible to work it out. But implicitly we pretend to coherence, implicitly we pretend to have methods of how to establish views, empirically or otherwise. In short, we implicitly pretend to have views rele-

vant to whatever we say. And those views are personal, not something found in libraries.

I'm inviting you to let us get hold of more of you; and not psychologically or socially, as Mr. So-and-So or Sir So-and-So, but to get to know how you perceive the world, its relation to yourself, the basic features of the condition of man as *you* experience them.

And I call this a philosophy and approximations to a total view.

Ayer: Oh, no, no, no.

Naess: Now you try to take that back?

Ayer: No, no, no.

Naess: You have said I don't have . . .

Ayer: No I don't take it back. Let me put it this way. I don't think that the term *total philosophy* . . .

Naess: Total view.

Ayer: . . . has any very useful application. What would having a total philosophy imply? Assuming that you do and I don't, in what way, in what concrete way, do we differ? I mean, I also have opinions about politics, ethics, aesthetics and express them and act on them. But these are not part of a total philosophy in your sense. How would I have to change, either in these opinions or in the metalanguage, in order to have a total philosophy in your sense?

Elders: May I try to formulate a question by which you could perhaps illustrate your point of view? Does your offensive nonviolence, Mr. Naess, imply that you would prefer to be killed by someone else rather than kill someone else? Is it part of your philosophy?

Naess: It would be more than a preference, actually. It might be that I would prefer to kill the other person, but I value the preference negatively.

Norms have to do with evaluations, with pretensions to objectivity, rather than preferences. Let me formulate it thus: I hope I would prefer to be killed by someone else rather than to kill, and I *ought* to prefer it.

Elders: And this is a part of your philosophy?

Naess: Yes. And it has empirical, logical, methodological, ontological, et cetera, ramifications, like other philosophical issues. It belongs to a greater unity of opinions which *in part* are derived from certain principles of descriptive and normative kinds.

Elders: And how is it for you, Sir Alfred?

Ayer: I should, I think, disagree. Although it's a very difficult question, I can imagine situations certainly in which I should prefer to kill someone rather than be killed by them, in which I should in fact try to kill someone rather than allow him to kill me.

After all we were both, I assume, in the war and there these situations arose. But I don't see in fact how this fits in. Because supposing I gave a different answer from the answer that he gave or indeed suppose I gave the same one, how would this in either case be part or not be part of a total philosophy?

It might of course in some situations be an extremely important concrete moral question; but what I am denying when I reject that sort of philosophy is that the way either of us answers a question of this kind has any relation, any logical relation, to our views, for example, on probability or on the theory of knowledge, or on the mind-body question, even on such questions as the freedom of the will. Whatever our theoretical views about the freedom of the will, I can't see that they would settle a question of this kind one way or the other. I mean, we might both be determinists in theory and yet take different views about this; or we might one of us believe in free will, the other in determinism and take the same view. When I was sceptical and said you shouldn't have this total philosophy, what I meant was that I can't see what the links are supposed to be to make the totality.

But of course I have opinions on all these matters and very strong ones, although in this particular case I think I would probably dissent from you.

I think I'm not a total pacifist. I haven't been in the past, and I think I can imagine circumstances in which I shouldn't be in the future. I think if something like the Nazis were to reappear, I would want to defend myself against them as I did then.

Naess: There is a relation between not wanting to kill somebody else, even in a fight, and epistemology; because any question which you answer implies a methodology. And this also holds good for the question "Would you prefer to be killed rather than to kill?" In order to answer this I must have a kind of methodology to find out whether I would. All fields of inquiry are interrelated; therefore we implicitly must pretend to cover them all when giving any answer whatsoever. We presuppose a total survey from mathematics to politics.

Ayer: May I put this concretely? Suppose that either you or I held a physicalist's view of human beings, something like Gilbert Ryle's *The Concept of Mind*. Suppose you were a behaviorist and thought of the mind as the ghost in the machine and so on, do you think that this would then entail an answer one way or the other to your question? Do you think that Ryle, for example, is in some way logically committed to giving a different answer to this question from the one that you would give?

Naess: No, I don't think it would entail this. But I think that certain views cohere more or less and that it's the business of a philosopher today to try out to what extent they cohere; to what extent they're not only logically consistent, for that would leave us too free, but also coherent in their non-logical aspects.

Ayer: Do you think that this view of the mind would even favor one answer to this moral question more than another? I mean, could you deduce simply from Ryle's book, other than psychologically, even in a semilogical way, what moral position, what view he would take on this moral question?

Naess: I think that if you made different combinations of interpretations, it favors, so to speak statistically, the acceptance of violence. But we would be capable of reconstructing it in such a way that it would not favor violence.

And this is an important thing. A book like Ryle's leaves things implicit: presuppositions, postulates, methodological rules. No single, *definite* set can be said to be presumed; therefore there will be a plurality of interpretations and a plurality of reconstructions.

And I agree with you, it is too easy to talk about a total view and to say "I have one." I detest questions like "What is your total view?"

Ayer: Yes.

Naess: Yes.

Ayer: Well, there you see how much I sympathize with you.

Naess: We cannot have a total view in the sense that we are somehow inescapably linked to certain definite opinions; nor can we behave like a general surveying an army of possible views and pick out some, saying "these are my views"—the relationship between ourselves and our views is too intimate.

Ayer: I should have thought, in fact, that your general philosophical position, with which I sympathize, went entirely the opposite way, and that the tendency would be to see each question independently on its own merits; not to feel that you were committed by your answer to this one, by any answer to that one.

Naess: Not any longer.

Ayer: Not any longer?

Naess: No, because I feel that as a philosopher I am an acting person, not an abstract researcher. Even this discussion is not really some kind of contemplative affair; it is also a kind of continuous action all the time.

Ayer: Indeed, indeed. In certain things you then require more coherence in action than you do in theory. You don't mind your theories being incoherent, but you want your actions to be coherent.

Naess: In research I tend to adopt an almost playful attitude in the sense of looking at and pleurably contemplating more combinations of views than anybody else. More kinds of common sense even! But as an acting person I take a stand, I implicitly assume very many things, and with my Spinozist leanings toward integrity—being an integrated person as the most important thing—I'm now trying to close down on all these vagaries. I am inviting you to do the same.

Ayer: But, why should I . . .

Naess: As a person you may have such a high level of integration that if you took some years off and tried to meditate a little more, you would be able to articulate some of your basic evaluations. These are more than inclinations; Jaspers calls them *Einstellungen*. They determine or at least express an important part of what would be your total view.

Ayer: It's not a prospect that I find at all desirable. Failure to be articulate has never been my problem, I think.

Naess: I think so.

Ayer: Well, there are hidden problems perhaps, I don't know.

Naess: Too fast, you're too fast.

Ayer: Yes, but I say a lot of things twice, that's all right, I catch it on the second time 'round.

I don't know; why should integrity demand consistency? One thinks that it does, but why shouldn't one judge things differently when the circumstances are always different? Why shouldn't one have the same flexibility in one's moral and political judgments as one wants for one's theoretical ones? I suppose one thinks that people are insincere if they don't maintain similar opinions in similar cases; but then the question of even what cases are similar is theoretically difficult.

I don't know: I dislike what you have just said—I think it's really the first thing that you have said at all, that I *have* disliked. This seems to me to

be really a conception of, well, I don't mind if it's called philosophy or not, and I don't mean that someone's trying in all honesty to solve problems that he thinks important, theoretically important or even practically important, but that somehow this represents a kind of deep narcissism, a digging down into oneself, contemplating: I'm not concerned with this. All right, it is possible that if I spent a year meditating I should perhaps dig up some very pleasant things; I don't know, I don't care. I've got better things to do in a way. I've got this problem, that problem, the other problem. I've got a certain intelligence. I'm going to use it for as long as it lasts. And perhaps, when I'm gaga I'll start contemplating in your sense.

Naess: Too late!

Ayer: And of what interest will that be to anybody?

Elders: I'll ask the same question, but not on a personal level. Would you say, Mr. Naess, that in your total philosophy intellectuals have a special responsibility at this moment?

Naess: Yes, because they are highly articulate. They are trained at universities in situations where they have at least three-quarters of an hour to think what could be argued against this, what could be argued against that; they get to be narrow and clever, too clever. I think that intellectuals might consider their intellects in a more Spinozistic way, as *intellectus* in the Spinoza way, and cultivate *amor intellectualis*.

Elders: Can you translate it?

Naess: *Amor intellectualis* would be a kind of loving attitude toward what you have insight into, while considering it in an extremely wide perspective. And intellectuals might do this without making the terrible mistake of becoming sentimental or fanatical. They would be able to say things to people in a more direct way and to articulate evaluations, their attitudes—*Einstellungen* or total attitudes—in a very forceful way while at the same time using some of the, in a narrow sense, intellectual training they have acquired in the universities.

They should be able to make us feel that to elaborate total views that are not expressive of something like “I am more clever than you are” is neither portentous nor necessarily favors some kind of fanaticism. When I say that you are, perhaps, deficient in articulation, it is because I feel you jump too fast to particular opinions on so-called facts, instead of taking a broad view and letting yourself say things which sound portentous and which might make you sound like a rhetorician or a politician, or even a prophet.

In this way I think that the intellectual of today, and especially the philosophically educated one, has a larger and wider function than that of being analytically minded. I’m sorry I use that catchphrase.

Ayer: Well, I don’t disagree with you on the question he asked. I do think that intellectuals obviously have a responsibility to do their job as they see it, and as well as they can do it; and also, I think, a social responsibility. I’m not a believer in the ivory tower at all; I think that anyone who has the capacity to think and to reason and perhaps believes, rightly or wrongly, that he can see things clearly, *should* try to contribute to social and even to political questions, so I don’t in the least dissent from you there. I don’t think that we quarrel at all about what we should be doing. What I think we may quarrel about is perhaps *how* we should do our job, and you might think that I do it in the wrong way.

Naess: Well, couldn’t you send me a copy of a speech made by you about a political situation?

Ayer: Indeed, I could send many. I mean, I’m constantly doing this; I’ve even stood for office, but I lost. I’ve stood on soapboxes on street corners. . . .

Naess: And there you use descriptions and norms.

Ayer: Ah, mainly normative, my language is then pretty emotive.

Naess: May I ask for instance, could you act as if you were now on a political platform? Say something real, “Bang!” like this.

Ayer: Well, I think that you can’t. Political speeches are not made in the ab-

stract. But if I knew local politics, I daresay I could make quite an effective political speech. I would point out how one side was acting in its own interest, more than the other, and how such and such a measure was perhaps an attempt to preserve privileges, or was associated with corruption, and all this would be highly charged emotionally.

Of course, we have to have facts behind it; it's no good saying so-and-so is corrupt unless you produce some evidence. But these two elements are mixed, obviously; and political speech has got to be factual, but with emotive overtones.

Elders: What's your attitude toward the Common Market?

Ayer: This I regard as a factual and technical question. I'm emotionally in favor of it, in the sense that I'm in favor certainly of larger units, against nationalism.

But economically I simply don't know; whether from the point of view of the ordinary Englishman in the street the economic price will become too high or not. And the economists are totally in disagreement. So, as a rational man, I suspend judgment. But I myself, if you like, feel European. I am by origin not purely English, I have some French blood, even on my mother's side Dutch, and therefore I'm emotionally in favor of a larger unit.

But I think this is partly a question of fact where I acknowledge ignorance. Whereas Naess, with his total philosophy, brings in different little facts. If he doesn't believe in facts, then why should he joke about them in this issue?

Naess: This is rhetoric, isn't it? [*Laughter.*]

Ayer: Of course it was, yes.

Naess: You shouldn't immediately give up so quickly in this way. Behind the rhetoric there are sets of value judgments.

I'm in a fight against Norway joining the Common Market. And one of the main things I'm against is putting larger units in place of smaller ones. I think that the larger units achieve greater technological advances and larger units of production instead of getting together with other peo-

ple in a nice personal way. We will get bigger markets, more standardized products, and we will take over some clever ideas from British universities instead of using our own less clever ideas about the university.

Ayer: I would think that some ideas from Norwegian universities might even be more clever than the ones I get at Oxford.

Naess: I doubt it, really. On the whole we are not clever, but we are provincial in the good sense of living our own way undisturbed by pressures from the great centers.

For me the question of whether to join the Common Market is not merely a factual and technical question. I am trying to connect my fight against the Common Market with basic evaluations. What are our value priorities? I see other people without analytical training taking up a philosophical point of view. I try to help them articulate their implicit systems in order to connect their ways of feeling with ways of asserting and evaluating things. Doing this I still feel myself to be philosophical and intellectual, whereas you would say it's more emotional, it's my emotional inclinations.

Ayer: No, I don't think so: on the contrary. I just said I thought it was partly a rational question, but I suspended judgment because I don't believe I have enough evidence. I mean I don't let my emotions dominate me here, because emotionally I'm attracted to the idea, but I suspend judgment as I'm not convinced of it intellectually.

Elders: So you couldn't be a good politician?

Ayer: I'd be a rotten politician, yes.

Naess: Just a minute. You couldn't be convinced intellectually? There I think you again use too narrow a concept of intellect. . . .

Ayer: No, I mean that if I were to take a final decision, it would depend, in part, upon the answers to certain economic questions, to which I don't think I know the answers.

Naess: Well, again you are displaying something narrow, I think—no, not narrow, but something peculiarly empirical—when you talk of a final judgment. But I can't make a final judgment about anything political, in a sense, because all the time that I am acting and being acted upon, here, all my judgments will be provisional.

But in spite of being decidedly against the Common Market, I could say that the range of facts known to me is probably narrower than yours; I know perhaps less about the Common Market. Decisions cannot wait until all the facts are gathered: they are never all available.

Ayer: Well, I hope the judgment is only final in the sense in which the reaction might be irreversible.

Elders: Irreversible, yes. Well, perhaps I could now ask my final and I think most difficult question; a question about the audience: do you think we have managed to get through to the audience, both here and at home?

Ayer: Yes, I think, in part. I mean, how can one possibly tell? I do think we have got through to the audience here in the sense that nobody walked out, and nobody threw things.

But inasmuch as we were both talking seriously and saying things we believed and things that interested us, and on the whole not trying to score off one another but trying to get at what truth there is in these matters, then I should hope that this at least would get through.

And perhaps, when one looks at two philosophers talking, this is what one wants to get through: the idea that these questions are important, some idea of what sort of questions they are, and some idea that one can really seek the truth about them without, perhaps, any notions of personal advancement.

Elders: And you, Mr. Naess?

Naess: I trust that we have got through to a limited extent, of course. I feel sure many people have turned off and are looking at something else.

Elders: Well, may I now suggest that we have a short discussion with the

audience? Perhaps we could agree about time. I suggest a discussion of half an hour.

Ayer: It has taken very long already.

Elders: You would like to relax a little?

Ayer: I must say it was not an easy passage of time.

Elders: Yet you have not walked out, Sir Alfred, after an hour and ten minutes. Well, may I have the first question?

Ayer: Get one done, yes.

Question: In the beginning, Sir Alfred, you gave a definition of philosophy that was entirely a negative definition. Philosophy is a kind of criticism, a criticism of belief and a criticism of knowledge, but I feel a certain tension between that kind of definition of philosophy and the opinions on everyday matters that you have and that you derive from what you call natural belief, or what is part of natural belief.

Ayer: Or common sense.

Question: Well, what is the relation between that positive conception of a rational belief or a rational certainty of the world that you have, and your negative definition of philosophy? And that question is related to another one—and here I feel that, perhaps, Mr. Naess would have another opinion—namely that natural belief is a thing which for itself has a criterion; you have criteria in order to be certain about certain things. But there can be different kinds of certainty, and so different kinds of natural belief. Why do you have this kind of natural belief and not another?

I don't know if this is perfectly clear, but I could elucidate this by giving an example. For instance, I imagine that I believe in ghosts, or I believe in the existence of Australia, where I have never been. I could give criteria for believing in ghosts, as I could give criteria for believing that Australia exists.

They would be the same kind of criteria. I've never seen either of them, never perceived them, never heard them, but I've read about Australia, and I've read about ghosts.

And I think that if you conceive natural belief in that way, then it could be possible to have another kind of natural belief; for instance in werewolves. I could be instantly afraid of you, for instance, because I saw a certain glance in your eyes which would be for me an indication that you were a werewolf.

Elders: Is the question clear?

Ayer: Yes, it's clear to me, I think. On the first part, I didn't intend my definition to be a purely negative one, and wouldn't in fact think it to be so. I mean that in one's questioning of accepted beliefs, or really of the criteria underlining accepted beliefs, one's attempt to clarify concepts, one can quite often come up with a positive answer. And I think there are examples in the history of philosophy; for example, Hume clarified the concept of cause, and I think that as a result of Hume's work one understands much better than people understood before what is involved in causation. I think he showed that the popular concept of causation was, to a very large extent, if you like, superstitious; but that there is then a residue remaining that can be clarified and be made quite precise. And I think, for example, that the concept of truth has been clarified, first by Aristotle and more recently by Tarski and so on; and, at present, I am myself working on the concept of probability and other people have worked on it. And I think that through this, one often arrives at something positive.

I don't at all want to say that one has to come to rest in scepticism, but only that scepticism was a kind of challenge posed to the philosopher, one that sometimes he didn't need, sometimes he left alone, but sometimes at least it provoked him into providing an answer, which was at least provisionally acceptable. I think I agree with Naess here that it's always only provisional.

I think the second half of your question was in fact very important and profound, because I think there is a kind of relativism here that is in a sense inescapable. The reason why we all believe in Australia when many of us haven't been there, is that it fits in with our general conceptual scheme;

there is nothing surprising to us that there should be a country on the other side of the world. We have a spatio-temporal framework into which you fit things: we already have a scientific, and after all, very fine, well-tested belief that the earth is round, so that there should be a country at the antipodes is something that comes quite naturally to us, so that here we accept testimony; we could go there and see for ourselves, but we don't bother to.

Now ghosts, even though they might be well attested—let's assume, for the sake of your question, that the evidence in favor of apparitions is even stronger than it is, or, much stronger than it is—there we become more cautious because it doesn't fit into our way of organizing the world.

Now you might say, Why not? After all, this has been true of some primitive peoples, so why don't I see you, not just as another man, but as, potentially, a werewolf, a being with all sorts of magical powers and so on?

Now, this could be a way of organizing my experience and it's a way in which people of other communities have, to some extent, organized their experience; and, in a sense, I can't refute it except by begging the question against it; except by assuming all sorts of metalogical criteria which are inconsistent with it.

So, in the last resort, I think, the answer here is pragmatic, in the way that it seems to me that, with a system of explanation of the sort I have, I explain phenomena more satisfactorily, I make more successful predictions than I do with an animistic system.

But if someone likes to see the world animistically, I don't think that I can refute him, because, as Naess pointed out in our discussion earlier on, the notion of fact is itself a dubious one, itself infected by theory. And I could say, well . . .

Elders: You've nearly converted him.

Ayer: . . . in a sense I'm more successful with my type of theory than he would be with his.

Elders: Well, Sir Alfred, he has nearly converted you.

Naess: No, no, what I would say is that I listened with pleasure because there you used some kind of a concept of *total view*. And so I congratulate

EMPIRICISM, POSSIBILISM, AND PLURALISM

you for making Sir Alfred show in practice that he is very near to thinking in terms of total view.

Ayer: Oh, in this sense, if you like to think of one's language and what's implied by one's language and one's general method as a total view, then certainly. I think connections are much looser within the conceptual system than you're making them out to be. But to this extent, certainly.

Elders: Ladies and gentlemen, this has to be the end of this debate. Sir Alfred, Mr. Naess, thank you very much for your total, clear discussion, on behalf of the audience, here and at home.

The Spirit of the Vienna Circle Devoted to Questions of *Lebens-* and *Weltauffassung*

Attitude Toward Research and Cooperation Within the Vienna Circle

The history of the Vienna Circle is bound up with what was called the *Wissenschaftliche Weltauffassung*. Given, however, the requirements of the members when it came to deciding whether or not a sentence expressed scientific knowledge, the basic sentences expressing a *Lebens- und Weltauffassung* would scarcely qualify as such, nor would hypotheses about a scientific worldview. The *Wissenschaftlichkeit* of physicalism, logical behaviorism, logical syntax, unity of science, were hypothetical at best, and in my opinion should not be identified with the total philosophical enterprise of the Vienna Circle. To its strictly speaking *philosophical* enterprise I attribute a certain kind of scientific or research *attitude* and *clarity* as much as any set of philosophical opinions of a substantial sort.

As I see it, the members excelled in clarity and in fairness and collaboration in debates. These characteristics they, like myself, found most effective and ethically acceptable among ardent “scientific” researchers. More-

Arne Naess’s contribution was read to the symposium “Wissenschaft als Kultur—Österreichs Beitrag zur Moderne,” organized by the Vienna Circle Institute as part of the “Focus on Austria” of the 1995 Frankfurt Book Fair. The German contributions were published in *Wissenschaft als Kultur: Österreichs Beitrag zur Moderne*, edited by Friedrich Stadler, vol. 6 of the *Veröffentlichungen des Instituts Wiener Kreis* (Vienna and New York: Springer, 1997).

This article was reprinted with permission from *Game Theory, Experience, Rationality*, edited by W. Leinfellner and E. Köhler (Dordrecht, Netherlands: Kluwer Academic Publishers, 1998), 359–67.

over—and this was unique in Europe—this admirable way of communication, of collaboration among very different personalities from widely differing backgrounds—was applied to philosophical problems.

I wrote about the above-mentioned aspect of the Vienna Circle a couple of years ago.¹ Here I shall mention again only the circle's excellent technique of offering various formulations of a view in order to arrive at clarification of disagreements and agreements. A typical question in a debate was, Would you accept that one could express the view you have by the sentence S_2 rather than S_1 ? In my work within the realm of what I call total views, comprising the classical questions of *Lebens- und Weltauffassung*, I have been heavily influenced by what I personally experienced in the Schlick seminar in 1934 and 1935.

The term *total* ought to have a bad reputation in politics, but I am speaking of views: explicit *but mostly implicit*; *both* normative (How do you think you *ought* to live?) *and* descriptive (What are the basic features of the conditions of your life *and* life in general in what you think is reality?)

This kind of sentence was used when someone thought he disagreed with a speaker but saw a *possibility* of agreement if the speaker could accept a different formulation, S_2 .

In trying to express fragments of total views in systematic form, we need to make clear which statements are meant to be declarative and which normative. Accordingly, I place an exclamation mark at the end of sentences intended to express a "norm," in the sense of announcements that something ought to be, should be, etc., and imperatives of various kinds, *including rules*. A system containing at least one sentence with an exclamation mark, I call normative. Thus, a small, central part of my total view is expressed, mainly for didactic reasons, in only one philosophical sentence with an exclamation mark: the one-word sentence "Self-realization!" From the basic philosophical normative sentence "Self-realization!" *plus* a host of declarative sentences, conveniently called "hypotheses," I derive new norms.

One of the reasons that the Vienna Circle tended to dislike what I call total views is that it associated them with claims to absolute certainty and to dogmatic truths. To hold a total view, however, is compatible with being a sceptic, at least a sceptic of the Pyrrhonic kind: maintaining an *epoché* in relation to every absolute certainty or dogma.² It is normal to retain

certain basic attitudes year after year but to change some opinions practically daily.

Why shouldn't analytic clarity and the research attitude be applied in what I always have taken seriously, namely, most general orientations, and their manifestations in conflicts?

The Status of Basic Views on *Life and World Until Now*

Until the twentieth century *Lebens- und Weltauffassung* belonged to the central part of academic philosophy, and certainly to "philosophy" in a more general sense. Diogenes "in the barrel" expressed himself mainly through nonverbal behavior. He did not offer long, difficult arguments in favor of his *Lebens- und Weltauffassung*. This is one of the reasons that he is not accorded as many pages in textbooks of philosophy as are some of the other classical Greek philosophers. He is scorned as an academic philosopher, but nobody—and this is important for the current argumentation—contests that he was a philosopher.

In the great cultures of the East, in India and China, philosophy of life, of society and the cosmos, had an important function, and if we look up the names of the main figures, until recently, we are reminded of great teachers of how to live, and how not to live. Science did not play an important role.

What is the status of *Lebens- und Weltauffassung* today? The question comprises both academic and nonacademic philosophy. My answer is not uncommon and not original: the concern in academic philosophy is feeble, *sehr schwach*, but among people and in social debates, rather strong and getting stronger.

Sources of Currently Increasing Interest

The concerns that stimulate life- and worldview reflections today, especially in the *materially* richest countries, are widely recognized as important. Here is a short summary.

The movement from *Gemeinschaft* to *Gesellschaft*. Ferdinand Tönnies published his famous book contrasting *Gemeinschaft* and *Gesellschaft*, community and society, about 100 years ago. We live in a community when we have a positive feeling of having much together, being much together, do-

ing much together, occasionally helping one another. Now we, in the rich countries, live in a mere society when there is a system of rules binding people together in a more mechanical way: a common forum of decisions affecting competing group interests. I might call these societies pressure democracies, wherein powerful pressure groups protect vested interests and a police force, rather than a father, sets limits.

One may question whether we in the earlier twentieth century had much *Gemeinschaft*. In Norway we had a class society, but more than 80 per cent of the population lived in rural communities with a high degree of community. The important point is that the direction of development seems to be toward less and less community: toward individual *autonomy*, even within families. One should not rely on help; one needs no assistance; rely on psychiatrists and other functions of the state. Autonomy is clearly different from former ideals of individualism.

Another new term is *entrepreneurial culture*. Society must be organized in such a way that entrepreneurs enjoy better conditions for the realization of their ideas. What kind of ideas? Any noncriminal designs, it seems, but with emphasis on economic growth and competition.

Closely connected with concern about the disappearance or decrease of community is, of course, concern about mindless, physical violence: violence seemingly lacking motivation. What we conceive of as fellow human beings are not always seen as such, but as mere objects. There is also concern about criminality in general: the United States is leading the way with more than a million people in prison, a kind of place generally recognized as not highly conducive to change of lifestyle.

Then we have concerns of a philosophical kind, about mass media and the global force of advertisements now estimated "to cost" about a trillion U.S. dollars annually. Mass media are ethically, if not neutral, at least pressing for the least possible interference by any norms of an ethical and educational kind, and pressing for increased societal dependence on markets.

Many perceive a resulting threat of *Gleichschaltung*, a decrease of deepness in cultural differences, an increase of standardization in spite of a multiplicity of tiny subcultures, especially in rich, great cities.

I now go back to the question of advertising. The private producers of goods and services on the market very naturally try to increase their sales and cannot be supposed to distinguish needs from desires, a philosophically

important distinction. The great thing is to create what people *feel* to be needs. It is now recognized that growing material so-called needs increase ecological unsustainability. Because I have worked for more than twenty years in this problem area, I shall go into it in some detail.

In 1972 the Club of Rome published its important *Limits to Growth*. In 1992, two members of the group, Meadows and Jørgen Randers, wrote the sequel *Beyond the Limits*. It is an even more important book, showing with a great number of diagrams that curves that should go up actually go down, and curves that should go down, go up.

The turn from increasing to decreasing unsustainability is not yet generally recognized to require in the rich countries a formidable change in average lifestyle. In addition, the rich countries must try to inhibit the increase of the material standard of living occurring in Southeast Asia, China, and other parts of the globe. Even if the rich nations succeed in this, the impact on ecosystems by, say, the 800 million richest people may surely reduce the richness (abundance) and diversity of life on Earth.

A new philosophical situation has arisen in the last part of the twentieth century. We have to take into consideration five warnings:

1. Ecological unsustainability is increasing.
2. People in the rich countries live (on average) in a way in which they cannot seriously wish that others, who would also like to live that way, will actually be able to live.
3. Decreasing the growth of unsustainability implies decreasing material standards of living in the rich countries.
4. Most of the cost in work and money necessary to change from increasing to decreasing unsustainability must be furnished by the rich countries.
5. Any delay increases the cost exponentially.

In 1998, the Worldwatch Institute roughly estimated the cost of a change from increasing to decreasing unsustainability: about 17 percent of the sum of global military investment at the time, \$149 billion (American) a year. Today (1999), a rough estimate may have reached the sum of \$200–250 billion. It is a vast sum, but not overwhelming.

A concept introduced by Immanuel Kant deserves close inspection to-

day. It is found in one of his early works, and few people seem to be aware of its existence. It is a concept of a *beautiful* action as essentially different from a moral action. An action is moral if it is *only* motivated by respect for the moral law. If we do exactly what is required by that law, but out of some other inclination (*Neigung*), then we do not act morally. Kant then goes on to say that if we act so as to satisfy the law, but also out of positive inclination, then we act *beautifully*.

Who would not like to act beautifully? From the point of view of ethics, as many of us see the situation today, the way to proceed in overcoming the great evils is not to preach but to find ways to describe the goals and the means to those goals so that they are *attractive*. This is difficult, but not impossible.

The five warnings are of a character that requires philosophical reflection along predominantly new lines.

The worldview, the *Weltauffassung*, centers on our world, conceived as our planet *Earth*, not the cosmos. How do we personally experience our participation in changing the life conditions on the planet, the rapid decrease of biodiversity and animal abundance and habitats, the increase of the domination of human beings over increasing areas of the planet? How do we experience the present social and political incapability to meet the challenge?

What kinds of ontology, epistemology, and ethics are conducive to strengthening the motivation of large-scale measures to ensure a change from increasing to decreasing unsustainability?

Also from questions essentially having to do with our *Weltauffassung*, we are led to questions of *Lebensanschauung*: in the rich nations, how to apply slogans like "Rich life, simple means," that is, means requiring less use of energy, less polluting, less waste, etc.; in the poor countries, how to increase the material standard of living but avoid development in the direction adopted by the rich countries—in short, how to implement the increase by "leapfrogging" the way leading to the rich countries' unsustainability.

Of the many contributions to what sometimes are called ecophilosophy and ecosophy I might mention the concept of the ecological self. As far back as Aristotle (in the West) we have declared humankind to be "special animals," or better, "social living beings." Human beings are, from one

very special point of view, highly mobile parts of the surface and lower atmosphere of our planet: they are the only parts that somehow perceive all other parts and appreciate them.

An extremely important, more or less spontaneous process is that of *identification* with other forms of life, that is, a perception of animals as in some ways like us, a perception that one can do something for their sake, that they, like us, have needs and interests. Philosophy of life has now a new social and political impact. Those who strongly appreciate life on the planet and strongly identify with animals and plants, whether those life-forms are in a narrow sense useful or not, are active in the effort to change lifestyles, institutions, and politics in the direction of sustainability. Important also is that they look for a gain in quality of life whenever possible from every step toward responsible ecological policy and are willing at any time to give up much of the typical rich country's goodies.

Green politics, with a capital *G*, is only one point of so-called ecosophies, total views in part inspired by work in favor of overcoming the ecological crisis. One may, of course, be an activist in Green political contexts without referring to, or being motivated by, a philosophy of life or worldview. Those who do have such a worldview, I call supporters of the deep ecology movement. Deepness is in this context defined in terms of chains of premise-conclusion relations. The supporters are in part motivated by their ultimate premises, their ultimate norms, and their descriptive views of the world. In short, they involve their *Lebens- und Weltauffassung*.

Why did not conditions lead earlier in the twentieth century to a philosophical awakening? One factor was a focus on language rather than on life, society, and the world.

The detrimental focus on language started explosively with Wittgenstein's *Tractatus logico-philosophicus* and logical empiricism. According to Rudolf Carnap, human systematic knowledge was, roughly speaking, of two kinds, the scientific and the syntactic. Questions of philosophy were in part reduced to logical syntax, in part dismissed as cognitively meaningless but emotionally important. With *Tractatus*, questions of value, of normativity, of ethics, and therefore also of politics were shoved into a sphere of mystery. There was no place for philosophical *research*. In the 1940s the anti-research attitude was consolidated with Wittgenstein's *Philosophical Investigations* and the ordinary-language movement. Empirical *research* on lan-

guage was shunned or deemed philosophically unnecessary. It was felt that intelligent reflection and intuitions concerning one's own language should be enough to solve, or dissolve, traditional philosophical problems. This trend is, if no longer dominant, very much alive at the close of the century. Philosophy professors still talk in terms of "getting the fly out of the bottle," that is, through considerations of language to set people free from warring about what were, for more than 2,000 years, considered to be great, universal philosophical problems in both the West and the East.

Less serious, but not without influence, is a quasi-philosophical trend that tries without much success to undermine belief in value priorities and the search for truth. Its adherents scorn any broad and deep movement that attempts to come nearer to solutions of great problems: of peace; of unacceptable, desperate poverty and oppression; of the ecological crisis. Instead of systematic approaches, we should limit ourselves to small narratives and cultural conversations!

So far I have talked about *Lebens- und Weltauffassung* in general terms. Now I shall exemplify what I mean by pointing to Spinoza. This thinker was venerated by members of the Vienna Circle, but the tendency was to consider his problems, insofar as they were real, to belong to psychology and the social sciences. I call my total view—if I can be said to have one—Spinozistic. I refer to a class of total views comprising variations of interpretations, elaborations, and reconstructions of Spinoza's system as formulated (mainly) in his *Ethics*. The term *reconstruction* I introduce in order to characterize interpretations of the text that Spinoza himself in part would presumably reject, but that the text admits.

It is my contention that the way I work shows the influence of the spirit of the Vienna Circle.

One may even say that this spirit is traceable in many ways, and that it provokes negative reactions of the same sort that we experienced in the 1930s: the intrusion of tools such as symbols used in symbolic logic into humanistic studies, taking definition and deduction seriously, and related "hard" ways of thinking. One of the characteristic traits of my study of Spinoza is that I take his definitions and definition-like ("definitoid") sentences seriously. If a sentence is a definition in a certain narrow sense, it implies that one may substitute the definiens expression for the definiendum expression, and vice versa, in the relevant text (in my case, the *Ethics* of

Spinoza) without changing the intended meaning. The style of the text may be heavily damaged in this process, because the definiens expression may be complicated, perhaps consisting of 100 words, whereas the definiendum expression (a sentence or a term) may consist of only one or two—but that is irrelevant. Spinoza uses about a dozen sentences that may imply either complete or not-complete substitutability. Thus, if he says that something, x , is *the same as* something else, y , he may roughly mean what I would declare by saying that x and y *denote* the same (but that “ x ” and “ y ” do not necessarily *connote* the same). There would scarcely be complete substitutability. Such substitutability *may* sometimes be complete, because he in other places in his texts uses stronger expressions to identify the particular x and y .

Noting the occurrence of the definitoid sentences, I work with a list of 243 definitoid sentences. Some are slightly reconstructed. They are standardized and said to announce “equivalences” among *centrally important* terms in the *Ethics*.

Through the use of the equivalences, I leave the words *Deus* (God) and *substantia* (substance) out in my version of parts of the *Ethics*. In Spinoza’s day one could scarcely dispense with those words, but today we can, and *the perfectly immanent God* of Spinoza invites us to eliminate the words that for most people denote transcendental entities. Speaking about entities, I use Occam’s razor and the second “definition” (*definitio*) in part I of the *Ethics* to eliminate the word *essence*. Incidentally, a modern logically conscious reader would tend to say that that “definition” is two definitions connected with “or” (*vel*):

II. I say that to the essence of anything pertains that, which being given the thing itself is necessarily posited, and, being taken away, the thing is necessarily taken away; or, in other words, that without which the thing can neither be nor be conceived, and which in its turn cannot be nor be conceived without the thing.

What Spinoza calls *definitio* is transformed in this case into two equivalence sentences implying universal substitutability in the text.

Using Spinoza’s definitions in this way, the *Ethics* can be “reconstructed,” not violating the text at any point. Spinoza would personally object to some of the reformulations, I presume. It would depend in part on

which stage of his life we refer to. In his last years he would perhaps have tolerated more of the changes than in his ardent youth.

The intricate web of the *most* central terms (about fifty) and their equivalences can be surveyed in its fullness through the use of symbolic logic. I use only propositional logic and predicate logic. I do not see how we can conveniently keep more than a thousand relations in mind without such an instrument. In those not acquainted with logic, however, the symbols tend to arouse negative feelings.

Of the terms that are connected with others through equivalence relations, I may mention the following: *acquiescentia* (5 relations), *aeternitas* (5), *affectus* (19), *amor* (10), *anima* (8), *bonum* (7), *causa* (21), *conatus* (16), *libertas* (3), *potentia* (32), *ratio* (30), *virtus* (18), *volitio* (3). About 100 terms in the *Ethics* are connected with one or more definition-like sentences. It is often said about certain philosophers that their vision is fundamentally simple and “one.” The equivalences testify to that. “To be in itself” is equivalent to “to be able to be conceived through itself,” which is equivalent to “freedom,” which is equivalent to “to be self-caused,” and so on. The kind and intimacy of the equivalences show great variation, however.

Two years after publication of my book presenting “the structure of a central part of Spinoza’s *Ethics*,” the tricentennial of Spinoza’s death was commemorated in Amsterdam. Here he was laid to rest in the Nieuwe Church. I felt it to be a vindication of the acceptability of my sort of analytical approach to his supreme work that I was invited to deliver the speech in that church. Even if no other Spinoza scholars have so far taken up work of my kind, I believe in a great future of analytical clarity in life- and worldview philosophy. Announce a lecture on Spinoza’s immanent concept of God and you may expect 20 students to come, but 200 may show up. Logical clarity and empirical work have a place *within* the framework of creative metaphysics.

Spinoza’s theorems about the favorable function of active emotions on the way to higher degrees of freedom are in principle testable empirical hypotheses and at the same time genuine parts of his metaphysical system. This was not denied by Vienna Circle members. It is a grave misunderstanding that the text of the *Ethics* is somehow deductive, or at least meant to be deductive. Of its five parts, part III and the lengthy part IV are full of empirical hypotheses. If the interest in them had been great enough, the work could have started to try to devise tests.

The limited empirical attitude of some of the members of the Vienna Circle showed itself in discussions of whether Alfred Tarski's work on the concept of truth furnished an adequate definition of truth. The conclusion Rudolf Carnap and others reached seemed to be that *logical* analysis showed it to be adequate. My view was that adequacy implied agreement with at least one way in which the words *true*, *false*, *wahr*, *falsch*, etc., actually have been used in speech and in texts. Only empirical research could, as I saw it, establish the *limits of the domain* of actual occurrences of the words within which the Tarski definition was adequate. I accept that there is such a domain and that it is an important domain, but also that there are several usages, even *within scientific texts*, that are outside the domain. This conclusion rests on the analysis of several hundred occurrences of *true*, *false*, *wahr*, *falsch*, and closely related words.

I mention this because empirical research on usages of a term indicates that an extended use of what might be called the Mach-Duhem-Poincaré theorem is warranted. Roughly speaking, it says that given a set of observations, there are indefinitely many mutually incompatible hypotheses that can be made to cover those observations satisfactorily. Studying occurrences of verbal utterances, we may find indefinitely many mutually incompatible sets of rules that cover these occurrences. One cannot simply "see" which rules the occurrences of the word *true* obey in ordinary speech or in scientific publications. It helps that the word belongs to one's mother tongue, but acquaintance is not the same as knowledge. The partial *adequacy* of Tarski's definition can only be corroborated through *research* that in part is empirical. Neither Tarski nor Carnap found it necessary to stimulate *empirical* research of this kind (as a genuine part of philosophical work).

In my reconstruction of a central part of the *Ethics*, I use about forty predicates; for example:

L(x)	x is free (<i>liber</i>), partially or totally, adequately or inadequately
Rat(xy)	x acts rationally in relation to y
NPC(xy)	x belongs to that without which y cannot be conceived
Mel(x)	x is in a state of melancholy

The "Mel(x)" could easily be omitted, but certain considerations of terminological symmetry made it natural to introduce it.

As could be predicted, when people from humanistic or literary back-

EMPIRICISM, POSSIBILISM, AND PLURALISM

grounds saw my text with its strange symbols, they mostly closed it in fear or disgust. (This at least is my suspicion.) Since I was seventeen years old I have read Spinoza in Latin and acquainted myself with some symbolic logic, and my total view, if there is any, clearly belongs to the class of Spinozisms. Consequently, for me a reconstruction, including the symbols, is significant in my practical life.³

Creativity and Gestalt Thinking

Long and intense training is required to express in words major aspects of a spontaneous experience. We enter a room and “the room” makes an impression upon us that we express in conventional terms by *light*, *dark*, *cozy*, *small*, *cold*, *beautiful*, and so on. These terms, however, are (of course) class terms. We experience an *instance* of coziness, not coziness in general. By uttering “cozy” we have only started on a verbal report, namely that of the particular content, different from any other, that makes us utter the general term *cozy*. Perhaps it was the first time we entered the room; the next ten times may also elicit a spontaneous experience, an aspect of which makes us utter, for example, “cozy as usual,” “cozier than usual,” or which does not make us utter anything like that. We may for a moment think “not *so* cozy,” or there is at least a faint or weak feeling of disappointment which seems to relate to a less vivid or less convincing impression of coziness.

It is common to look to poetry for vivid and beautiful verbal expressions of spontaneous experiences.

The yellow fog came creeping down
 The bridges, till the houses' walls
 Seemed changed to shadows and St. Paul's
 Loomed like a bubble o'er the town.
 (Oscar Wilde)

Some expressions reveal separation from the spontaneous: “seemed.” Others do not—for example, “yellow fog came creeping down” instead of

This article was reprinted with permission from *The Structuralist* 33/34 (1994): 51–52.

the reflective “yellow fog seemed to be creeping,” and “changed to shadows” instead of “looked like shadows” or “seemed to change to shadows.”

The poet makes us more or less adequately create spontaneous experiences, or better, elicit spontaneous experiences, some aspects of which are inspired by the poem. In a flash we see yellow fog creeping down.

Accomplished poets, writers of novels, and a variety of artists use words in brilliant ways to express aspects of their spontaneous experiences, but of course we all verbalize, however crudely or conventionally. A spontaneous experience may be of burning intensity but our words flat, dull, and conventional.

In the case of artistic expressions, creativity is obvious, and the spontaneous experiences are the obvious, infinitely rich source. Can the same be said of creativity in mathematical physics? The physicist is not asked to express a spontaneous experience, but his need to use vernacular terms such as *waves* and *particles* for immensely abstract entities reveals dependence on concrete contents of experience in order to create. What is called the function of imagination, whether in writing novels, inventing gadgets, or constructing physical theories, is to elicit spontaneous experience where we “see” something. Instead of keeping only to the algebra involved, the physicist sees the equation in the form of a “real” wave. However abstract the reasoning, the mind needs concrete contents. The world of metaphysics is polluted by creatures suggesting *aspects* of vivid spontaneous experiences.

Within contemporary literature loosely referred to as postmodern, we find interesting ways of speaking that *seem* to tell us that our society “constructs” reality. Expressions such as “the (dominant) conception of reality within a society” are avoided. It is sometimes suggested that we never experience reality as such because we are limited to what our texts and narratives instruct us about what is real.

Against this view it is pertinent to insist that personal spontaneous experiences (of gestalt character) acquaint us with the real. The richness of those experiences is such that verbalization can only refer to aspects of them. The gestalt character in an obvious way implies richness. When in a certain situation a subordinate tonal gestalt within Beethoven’s Fifth Symphony is experienced by a definite person who knows that symphony well, aspects of the whole symphony and perhaps aspects of recent experiences of going to a concert color the content of the *total* spontaneous experience.

The complexity may perhaps be said to preclude the formation of a text that adequately expresses the experience, that is, adequately describes the total spontaneous expressions (in their full richness). Rarely does a situation occur in which we are motivated to engage in such an endeavor. Moreover, the need to act requires us to focus on definite aspects of the spontaneous experiences. The yellow fog creeping down a bridge over the Thames *instantly* elicits a decision to wear a coat or some other decision.

It has been suggested that the immense power of the new forms of mass communication narrows down our conceptions of reality in such a decisive way that our spontaneous experiences reflect what is mass communicated, and our capacity is destroyed to experience anything that is squarely incompatible with mass media.

The importance of increasing our awareness of the influence of mass communication is obvious. It should not, however, diminish the trust we have that we are able to make full creative use of our access to reality through our own spontaneous experience. The confidence of having a *source* of creativity that never disappears (until our mental capacity completely disappears) might be undermined by speaking as if we are imprisoned in our conceptualizations—our socially accepted metaphors and texts. Spontaneous experience transcends personal, social, and cultural specifications. That is, any attempt to nail down the dynamic, process-oriented character of gestalt experience by specifying a person, a society, or a culture, pretending that the gestalts belong to a definite kind, is in vain. The attempts by historiographers to characterize epochs (the Renaissance, Baroque, Enlightenment, and Romantic periods, for example) are frowned upon by historians who delight in complexity, not uniformity, in irregularities as much as in regularities. When we conceive an event as part of a whole, for example, as part of a campaign or a war, the conception of the event is furnished with *emerging* properties. The event, defined in terms more or less common to the members of a group or society, becomes part of a social stereotype, but this does not totally inhibit the creation of nonstereotype gestalts. The range of creativity may be reduced, but it is not destroyed.

The formulation of cohesive communities and societies is said to depend on shared values, on consensus in vital matters of life. These have gestalt character, but even in traditional societies with stable shared values,

processes of change are going on. They depend on creativity, and the main source is the richness of spontaneous experiences.

If in a storm, for a moment I have the impression that a tree is going to hit me on the head, there are spontaneous experiences of tree-and-me, but in general, spontaneous experiences focusing on a tree do not also contain me. There is not a subject-object cleavage in every spontaneous experience, only in a small subgroup of them. *Cogito ergo sum* does not seem to hold necessarily unless an instance of cognition is a gestalt with a "me" as a subordinate gestalt. It is not easy to imagine, but a human being capable of focusing steadily on something else would be aware of a subject, a "me."

Children are apt to lose much of their creativity when they are repeatedly confronted with statements from adults such as "No, it is not *really* so." Consider a child who sees a dog as threatening. Instead of saying "You are *wrong*, the dog is not threatening," one may insist that it will not bite or do other things the child fears may happen next, or that running away is not advised.

The richness and intensity of spontaneous experiences often induce strong expectations about what will come next—they may induce spontaneous actions. Here the adults, with their largely socially determined common sense, are indispensable as guides. However, if they use terms such as *wrong*, *mistaken*, and *nonsense* or react with a laugh, the child starts to distrust what he experiences. He starts to believe in a social and objective reality that is only a kind of meeting point within a community, a consensus reality devoid of originality, and only a kind of a skeleton: a mass classification of items. "You ask what you see there? It is just a common daisy!" Spontaneous experience, however, is never *just* a specimen of a class, the vast *class* of daisies. What is experienced spontaneously is something that never has been experienced before and will never be experienced again.

The gestalt terminology helps us avoid the conception that "what there is" is a mass of things and their external relations. The relation between gestalts is that of more or less comprehensiveness, like the gestalt units within the larger units of Beethoven's Fifth Symphony. A performance of the symphony is only a collective name, socially essential, to assure geographical unambiguity.

What is experienced by a member of the audience is not simply the symphony, but the symphony in a setting that is peculiar to each member.

There will be a unique series of spontaneous experiences of gestalt character. A young composer listening will perhaps be inspired not to create within the style of Beethoven, but to write something in a grander style than he is accustomed to. He or she will treasure and recapture the total experiences. The other members of the audience may through their particular gestalt experiences increase what is called their originality. They communicate in less conventional terms and metaphors.

Education is officially concerned with learning, but unlearning is a phenomenon that ought to be taken more seriously. One learns to neglect certain aspects of spontaneous gestalt experience; certain, mostly very subordinate gestalts lead to socially advantageous actions. The larger frameworks are socially irrelevant, misleading—you will soon be called a dreamer if you stick closely to the more comprehensive or idiosyncratic aspects. Utilitarian, pragmatic, and practical concerns are like pressures reducing the intensity, normalizing the seemingly chaotic changes of what is experienced, standardizing and simplifying. We unlearn in a way in order to be useful citizens, but mostly or always at the cost of originality and creativity. What can be done in education is to oppose the extremes of unlearning and to try to enable children to change viewpoints from the action-oriented to the focus on gestalt experiences, and back again. As it is now in at least some industrial states—for example, the Scandinavian—education is increasingly utilitarian in spite of a material richness that should open great opportunity for a wider acceptance of the nonutilitarian.

Do We Know That Basic Norms Cannot Be True or False?

The question of whether norms can or cannot be true or false is largely discussed as if it were capable of a solution a priori.¹ In this paper I try to show that the traditional a priori arguments against the possibility that norms are true or false are not decisive and that a posteriori arguments may at least become relevant.

One of the main contentions in what follows is that if it can be the case that something ought to be, then it can be true that something ought to be, and that whether something is the case cannot be known a priori. Experience may disconfirm our hypotheses as to what is the case—if experience can disconfirm anything.

Another main contention is that in relation both to basic norms and to basic nonnormative statements of science, there are grave questions of justification that make the application of the terms *true* and *false* to them problematic. If the claim to truth-value of basic norms is as well (or badly) established as that of basic statements of science (and metascience), then the applicability of “true” and “false” to basic norms follows from their applicability to basic statements in the sciences.

A Priori Arguments

In a posteriori argumentation, conclusions have an inherently ad hoc character: future experience, the term taken in wide senses, may overturn them.

This article was reprinted with permission from *Theoria: A Swedish Journal of Philosophy* 25 (1959): 31–55. Parts of this paper, with slightly different conclusions, were published as an article in *Logique et analyse* 1 no. 1 (1958): 4–13.

Or, if one retains the conclusion, one may be forced to adopt increasingly complicated and arbitrary auxiliary hypotheses. The spirit of research on questions a posteriori shows itself in the systematic and careful way in which the researcher prepares himself for disconfirmation as a result of new observations. These may indeed overturn his ad hoc conclusions, but this does not impair his joy in a posteriori research. It is an essential part of the game.

In the debate concerning the objectivity of norms, there is very little reference to contemporary or future empirical research or to other sources by which to improve upon the certainty or accuracy of the arguments. One reason for this may be that main arguments have a strictly a priori character, or are believed to have that character.

What are now the main arguments (if any) that have a justifiable claim of being a priori?

Let us first declare that the term *a priori argument* will be used to express a concept such that whatever will be *observed* in the future, an a priori argument will remain relevant (or irrelevant), true (or false). It cannot possibly change relevance or truth-value because of such observation.

Such a concept of a priori does not have as conceptual characteristics generality, finality, or apodicticity. The *possibility* of verification or confirmation, falsification or disconfirmation by future action is not denied, but *observational* statements will not be relevant.

The irrelevance of future observation refers only to observations concerned with the phenomena about which the argument asserts something.

The Doctrine That Norms Cannot Be True or False

The prevalent tendency in Anglo-American and Scandinavian philosophy and social science is to question or deny the *possibility* of knowledge of a normative kind, for example, normative ethical knowledge. According to this dominant trend, we know or may know the shape of the Earth, but we do not know and will not possibly come to know whether one should act so “dass die Maxime deines Willens jederzeit zugleich als Prinzip einer allgemeinen Gesetzgebung dienen könne.” The difference is often expressed in condensed form by saying that whereas a proposition may be true or false, a norm cannot be true or false. A norm may be valid or invalid, but that kind

of validity is different from that of propositions, that is, different from truth.

Which are now the arguments put forth to strengthen the position that normative knowledge is impossible? In what follows we shall inspect a sample of proposed a priori reasons for the impossibility of basic norms being true or false. The sample includes an example of each of the main kinds or families of arguments put forth in contemporary philosophical debate, insofar as they can be isolated from their specific, usually very complicated, context. The arguments that clearly are meant to be a posteriori are not included. Thus, the argument of A. Ross (1945) concerning lack of agreement on the value qualities of objects is left out.²

An Argument from Logic or Semantics: Norms Are Not Propositions

Let us inspect the following argument: True and false are, as used philosophically, predicated only of propositions. Norms are not propositions. Ergo, norms cannot be true or false.

Two Counterarguments

There are two counterarguments to be mentioned at once. In framing the first counterargument in what follows, we presuppose that the expression “as used” means the same as “as actually used until now.” That is, the argument concerns the denotata, not connotation of truth or falsity.

If instances of the use of a predicate are known and arranged chronologically, we may at any definite time list common characteristics of the denotata. The next instance of use may, however, present a denotatum that lacks one or more of these characteristics. Even if it were the case that the denotata of the predicates “true” and “false” in philosophical literature always have been propositions, and norms are not propositions, this does not exclude the possibility that truth or falsity is predicated of a norm next time.

Some time ago, “carnivorous” in zoology expressed a predicate applied at that time only to animals. A materially adequate definition of “carnivorous” might therefore at that time include a restriction to animals. The ex-

tension of the predicate included only animals. Today we speak also of some carnivorous plants. If someone had eagerly proposed a definition such that the term *carnivorous plant* is contradictory, so much the worse for him!

It is not the business of philosophy to ossify terminological regularities. The argument that until now only propositions have been labeled "true" or "false," or that certain definitions of yesterday include a restriction to propositions, begs the question. It presupposes that those beliefs are true that make it convenient to adhere to a terminology that is under consideration. Now, this is a presupposition that may turn out to be false. If so, the definition of "truth" or of "proposition" may be changed with good reasons, reasons that are good because of certain changes in opinion, owing, for example, to new discoveries. In short, from premises telling us how the terms *true*, *false*, *norm*, and *proposition* have been used until now, we cannot conclude that norms can, or cannot, be true or false. This holds whatever such premises are telling us.

Now, if it were shown that norms might be true or false, the rules of ordinary logic could be applied to them. Norms derived from true basic norms plus hypotheses from various sciences would be true. Thus norms and (nonnormative) propositions could be treated in the same way within important considerations. If such a possibility were realized, it would furnish an argument for calling the norms propositions, that is, a good argument for reconsidering an old classification, adjusting the delimitation of classes of phenomena to new insights and changing terminology.

Summing up the first counterargument, it may be thus formulated: The fruitfulness or convenience of a classification system of entities into propositions and nonpropositions depends on certain things we do with propositions, certain operations, for example, applying the calculus of propositions to them. If norms may be treated as propositions in making deductions, this might be a good reason for revision of the *fundamentum divisionis*: we might then include norms in a broad class of entities, the class of entities capable of being true or false, a class covering both nonnormative propositions and what might be called normative propositions.

A second counterargument is relevant if truth-value of norms is rejected on the ground that it violates rules of vocabulary or (normal) definition: there are many proposals for definition of "norm" and "truth," none of which enjoys general consent among philosophers, but even if a now gener-

ally accepted definition ruled out the possibility of true or false norms, the terms *true*, *false*, and *norm* have for a long time been used in such ways that to speak about norms as true or false has not involved contradiction. It is a perfectly legitimate undertaking to study the relation of truth and normativity on the basis of the noncontradictory usages, thus rejecting a definition that within a certain time interval was generally accepted. In short, since the terms *true* and *norm* have been, and still are, used in ways such that “the norm *N* is true” will not constitute a contradiction, references to nominal definitions such as “the norm *N* is true” that represent contradictions in terms, cannot show or prove that norms cannot be true or false.

We admit that “norms cannot be true or false” is true in relation to all those systems of nominal definitions that make the sentence a *contradictio in adiecto* but add that these are not all systems, and that the other ones are in no bad relation to common usage.

Tentatively, we conclude that the first argument is a bad argument. It does not support an a priori rejection of there being true norms or genuine normative knowledge. It presupposes that the rejection has already been justified on some other basis.

A Semantical Argument: Norm Sentences Are Meaningless and Therefore Cannot Be True or False

Basic norms—or, more generally, pure norms—are expressive of feelings; they lack the symbol function characteristic of sentences expressing propositions. They may therefore be said to lack cognitive or theoretical meaning. Now, the predicates “true” and “false” apply only to cognitively meaningful statements. Their connotation or conceptual characteristics entail such a limitation. Therefore, basic norms cannot possibly be true or false.

Counterargument

The first premise involves two hypotheses in psychology or the social sciences: that norms are expressive of feelings and that they lack the symbol function. These are interesting working hypotheses, which perhaps may be strongly confirmed by future research. Actually, the first would be regarded as well confirmed by many psychologists. It is not clear, however, why the

function of expressing feeling should have lack of a symbol function as a necessary consequence. The second hypothesis is independent of the first.

Anyhow, both hypotheses are inadequate as part of an a priori argument. If the premise were established a priori, it might have been justified to use the strong expression “cannot possibly be true or false” in the conclusion. If, however, the premise in the future will only be strongly confirmed, the conclusion will only attain the status of a strongly confirmed hypothesis, useful only in a posteriori argumentation.

An Ontological Argument Against Normative Knowledge

Let us then proceed from the semantical or analytical argument to an ontological one: a true statement asserts of what is that it is and of what is not that it is not. In other words, it asserts that what is the case *is* the case and what *is not* the case is not the case. Or, truth is *adequatio rei et intellectus*—truth consists in agreement with reality.

These formulas (and others) are traditionally used in references to the so-called classical conception of truth.

Now, says the argument, take a norm stating that this or that *ought* to be. *Be* and *ought to be* are not the same; neither are *not to be* and *ought not to be*. The Aristotelian tradition thus implies that the norm cannot be true or false.

Moreover, the formula *adequatio rei et intellectus* presupposes a *res*, an object that our statement says something about. This object must actually be there, not only ought to be there. Similarly, the formula “agreement with reality” presupposes a reality or state of affairs about which we are saying something.

Now, according to the Aristotelian tradition, there do not exist any entities, either immanent in the world or transcending it, that are capable of forming the truth-condition for a norm.

Counterargument

Let us inspect the sentences “It is true that there are black swans” and “It is true that you ought to love your neighbor as yourself.” The classical, Aristotelian trend in definitions of truth admits the formula that it *is true that* there are black swans if it *is the case that* there are black swans. What is the

object, the res, the reality, with which the statement must agree in order to be true? It is the condition of something being so and not otherwise, that is, of something being the case. I think this answer does not amount to more than a repetition of the use of the expression "is the case that." The introduction of terms like *object* and *reality* suggests extension. Perhaps something may be the case without presupposing anything extended. If this possibility is rejected in advance, the discussion in this article is made pointless by an a priori postulate.

Semantically, the formula "if it is the case that x , then it is true that x " applies to the Golden Rule. We may say that *it is true that* you ought to love your neighbor as yourself, if it *is the case that* you ought to love him that much.³ If this is so, the norm asserts of what is, that it is. It does not say that actually you love your neighbor. The state of affairs, or reality, it designates is the one *that you ought* to love your neighbor. Compare the following way of speaking: "*Is it so* that you ought to love your neighbor? Yes *it is so*." If this "is" is too abstract, too insubstantial or shadowy to permit the terms *real* or *state of affairs*, let us drop those terms in this connection. "True" and "is the case" are good enough.

Correspondingly, a norm saying that you ought *not* to love your neighbor less than yourself, states of what is not so that it is not so. The Aristotelian definition of falsity applies, and so does the "is the case" formula. It is not the case that you ought to love him less than yourself.

The Aristotelian and other classical truth formulas lead us to assert that at least some norms are true, provided *it is the case* that we ought to act as the norms "tell us." Whether it is the case can hardly be decided by inspection of classical formulas of truth.

Among the kinds of doctrines traditionally used to support the claim that it may be the case and may be true, that something ought to be, one main kind is outstanding because of its long and distinguished history: the doctrines of ideas in some more or less Platonic versions. When they are applied to pure mathematics and logic, we get the doctrines of mathematical objects such as (nonphysical) circles or relations, classes, etc., as entities distinct from the relata and the class members taken separately.

Applied to norms, the doctrines of ideas may assert the existence of ought-relations or "*ideale Forderungen*," not further reducible. Among sociologists, Georg Simmel takes this view.⁴

The phrases *world of value*, *world of duties*, *world of norms* suggest Platonic objects in a normative heaven, and belief in such objects requires an imagination more religious than scientific. The belief in the possibility of normative knowledge does not require this imagination. It is enough, for example, to believe in the possibility of a kind of insight that Husserl has described in his account of ideal, apodictic laws. He refers to the principle of identity and analogous first principles that he believes can be *seen* to be valid by a confrontation *with what is the case*, with the “*Sachverhalt selbst*.” I cannot say that I find Husserl at all convincing, but it seems to me not unreasonable to suppose that there might be instances of pure intuitions of the phenomenological kind.⁵

If there were such intuitions, they would establish normative knowledge. In Husserl’s “meeting” with what is the case, there is no schism between a physical or perceived object and a mind, but an illuminating insight in which it is seen *that* something is the case. It is not the *something* that is illuminated but the *that*.

According to Platonism, the sentence “It is the case that the center of a circle halves all its diameters” may be as true or false as a statement about an ideal circle. According to Husserlian doctrines, it would rather be the logical relations between the definition of a circle and that which is asserted by the sentence that can be intuited. There is, strictly speaking, no need for ideal *circles* according to such doctrines. The ideal state of affairs does not require an object—a circle, or something else—that exhibits the state. The position that some norms possibly are true may thus be given a Husserlian color. “It is the case that you ought to realize yourself” might be a true or false statement about an ideal state of affairs of a normative kind.

Among the contemporary advocates of Platonic varieties of objectivism, Nicolai Hartmann might be mentioned. A couple of quotations will exhibit his way of thinking:

Ethik kann tatsächlich lehren, was sittlich gut ist, wie Geometrie lehren kann, was geometrisch wahr ist. Aber sie kann dem sittlichen Bewusstsein nichts aufdrängen, sondern es nur auf seine eigenen Inhalte und Prinzipien hinlenken. Sie kann nur aus ihm heraufholen, was in ihm enthalten ist. Auch hierin gleicht sie der reinen Mathematik. Der Unterschied ist nur, dass die Prinzipien und Inhalte, die sie ins Bewusstsein hebt, Gebote, Normen, Werte sind. Dem Inhalt nach also ist sie normativ, nicht aber der Methode oder der

Do We Know That Basic Norms Cannot Be True or False?

Art der “Lehre” nach. Denn die Apriorität der Einsicht und die Didaktik der Hinführung auf sie ist die gleiche hier wie dort. . . . Die ganze Verantwortung für Rechtmässigkeit und Objektivität des Wertungsmaßstabes fällt der eigentlich apriorischen Wertschau, d.h. letztlich dem Wertgefühl selbst zu.

(Hartmann 1949: 29, 127)

Das reale Sein also kann wohl Wertvolles enthalten, aber es kann kein Sollen enthalten. Es kann auch das Hintendieren als solches nicht aufnehmen, wenn nicht eines seiner eigenen Gebilde sich als tendenzfähig d.h. als aufnahmefähig für das Sollen erweist. Das Subjekt ist das Tendenzfähige—und so weit wir wissen können, das einzige Tendenzfähige—der realen Welt. Es allein kann das Sollen ins Sein ‘setzen’.

So Kommt es, dass das Sollen, obgleich es nicht im Subjekt wurzelt, ihm vielmehr als gestellte Anforderung gegenübertritt, dennoch als aktuelle Tendenz im realen Sein nur am Subjekt ansetzen und nur von ihm aus von Reales determinieren kann.

(Ibid., p. 182)

The chief difficulty in refuting a priori the contemporary Platonic or objectivistic views of values and norms lies in the claim that those views affirm the *existence* of something. In matters of ghosts, golden mountains, talking stones, and many other entities defined without internal contradictions, refutations are based on experience or, more generally, on a posteriori considerations of some sort. The refutations may be of crushing weight, making belief in the existence of the entities practically impossible, but they are not a priori refutations. “Think away” your experience until now, or imagine you have had other experiences, for example, those described by Husserl, and in other observational journals, and then your refutation would no longer hold. One may be convinced never to face such observational journals, but it seems difficult to find valid a priori justifications for this conviction.

If a Norm Is True, Is It Then Also a Description of Something?

Affirming the thesis that for all we know *it may be the case* that something ought to be, do we not also assert that, for all we know, normative propositions may be a subclass of descriptive sentences?

If one takes the view that all sentences of the kind “It is the case that A”

are descriptive and “*B* ought to be” is normative only insofar as it is *not* synonymous with “It is the case that *B* ought to be,” then we may answer affirmatively. Such a conclusion, however, would not alter the important conclusion that those sentences of the kind “*B* ought to be” that are synonymous with “It is the case that *B* ought to be” may be true or false. The proposed terminology would lead us to subsume an important class of ought-sentences under the concept of descriptive sentences—and why not?

Because of the importance of concepts of “norm” in debates on value nihilism, it may be worthwhile to discuss Harald Ofstad’s attempt to give a descriptive definition of “pure norm” adapted to the use it has received in the writings of the Uppsala philosophers.

In his article already referred to on Scandinavian philosophy, Ofstad defines “pure norm” in such a way that it excludes any norm that *may* be expressed by a declarative (descriptive) sentence:

A formulation given by a person is said to express a pure norm [for this person] if and only if the following two conditions are fulfilled:

1. The formulation must be synonymous for its giver with an imperative formulation, or with a formulation that says or denies that something ought to be done, or shall be done, or must be done, or that something has value or is good, or is bad, or is better than something else or the best of something.
2. The formulation must not be synonymous for its giver with a descriptive (declarative) sentence.

(Ofstad 1951: 46)

The terms *declarative* and *descriptive* admit different interpretations of importance for our present discussion. If *declarative* is defined as is customary in grammar, sentences such as “It is your duty to defend your fatherland” and “You ought to abstain from killing any human being” are declarative. Thus, all sentences fulfilling the first condition might turn out to violate the second condition with the exception of the imperatives.

If, on the other hand, *declarative* and *descriptive* are taken from terminological trends in value theory, the terms might as well be introduced by inserting a series of negations in (1). The formulations must not be synonymous with a formulation that neither says nor denies that something ought to be done, or that something shall be done, etc. Unhappily, there are no

suitable definitions of “descriptive” except in contrast to “normative” (or imperative).

It should be unnecessary to add that the term *pure norm* thus introduced is only precise enough for very modest purposes of exposition. The attempts to introduce more precise and at the same time fruitful concepts of “pure norm” or “genuine value judgment” have been, so far as I can judge, rather unsuccessful.

Now, how is “It is the case that *B* ought to be” to be classified? Empirical studies show that for many people in many situations the sentence is synonymous or near-synonymous with “*B* ought to be,” expressing forcefully the intended objective validity of the norm. Using Ofstad’s descriptive definition, we would unhesitatingly say that the sentence fulfills the first condition, but how should we tackle the question of whether it is synonymous with a declarative sentence? In the absence of any suitable definition of *declarative*, we might say that the first part of the sentence *sounds* declarative and the second does not.

If a declarative sentence is defined as a sentence expressing that something is the case, the sentence “It is the case that *B* ought to be” is declarative. For those who use that sentence synonymously with “*B* ought to be,” this latter sentence will also be declarative. For people who use such a sentence as indicated by Charles L. Stevenson and others, it would not be declarative.

How Strongly Should Normative Insights Motivate Action?

One of Alf Ross’s main conclusions concerning propositions of value is that they cannot be true or false and that if they could, they would not have a normative function other than that which declarative sentences sometimes do have. Even if there were objective values, says Ross,

[T]he *apprehension* of value would not be “practical” or “normative” in any other sense than all cognition is. For any cognition can be called “practical” or “normative” in the sense that on the assumption of a given aim of aspiration the insight into a certain theoretical state of affairs has a normative effect on behaviour. Thus, for instance, the theoretical insight that water boils at 100° C. will determine the behaviour of the person who wishes to make the water boil. The theoretical insight may be transformed into a hypothetical norm (in the present case: if you wish to bring water to the boil, you must heat it to

100° C). It may also be expressed thus: *under suitable circumstances all theoretical insight possesses technico-normative significance.*

And the apprehension of value would have no other normative significance. The objective values, to the person not interested at the outset, would practically be a matter of complete indifference. How do these values concern my practical attitude? I may for instance accept the theoretical assertion that lying has the quality of “odiousness” and at the same time without any sort of inconsistency lie on a large scale.

(Ross 1945)

It seems here that Ross works with a concept of normative such that a sentence “Lying is odious” would have a normative function and express a true norm only if insight into its truth would prevent a person from lying, or if it agitates the speaker or listener. About a preacher’s sermon it may, however, in all sincerity be asserted that it was true what he said, but it was boring and left the listeners indifferent. We may also sometimes say, “I know what I now *ought* to do, but I do not *want* to do it.” This, and similar utterances of occasional practical indifference toward what is sincerely believed to be true, cannot easily be taken as conclusive argument against the beliefs. Value objectivists stress the intense prescriptive character (“*Forderungs*-character”) associated with genuine acts of value cognition, but not to the extent that the subject is by necessity permanently and strongly motivated to satisfy the demands associated with the cognitions.⁶ Thus, I do not think that Ross’s argument hits the mark. Knowledge of values could be of great importance in practice even if it did not invariably elicit a behavior in accordance with the insight.

A Priorism Incompatible with Empiricism

In light of the foregoing, my tentative position will be that *for all we know* some norms may be true or false and that consequently normative knowledge may in principle be obtainable, but perhaps never obtained.

Why should one bother with the possibility of such knowledge if one happens to be more or less convinced that there is none?

In my own case I bother with this possibility because I am not convinced that human beings might not have had, or might not in the future acquire, normative knowledge. They will perhaps be able to verify or falsify

a norm, or at least confirm or disconfirm it to a degree of practical importance. I am neither certain that there are normative truths to be verified or confirmed nor sure that there are not.

The climate in Anglo-American and Scandinavian analytical philosophy seems to have been favorable to a priori arguments against the objectivity or truth of norms or values. Those, however, who are inclined toward empirical trends in philosophy cannot but view with suspicion the dominance of a priorism, and this suspicion will concern counterarguments as strongly as pro-arguments. It is the particular job of empiricism to leave questions open if no decisive arguments are at hand.

Ross seems to view his inquiry into the nature of value as a crusade against a priorism. Of what kind, then, are his own arguments? They derive from neither mathematics nor (formal) logic. He calls his method logical analysis, but from which kinds of inquiry research does this method get its authority? It seems to me that in combating a priorism in one field, he introduces it in another. He does not specify any empirical research that might settle questions a posteriori.

Must Normative Objectivism Lead to Fanaticism?

The following discussion is not intended to be a continuation of the argument. It states a causal hypothesis concerning conditions that have undermined objectivism. It has been felt that dogmatism and fanaticism in religion and morals, and absolutism and totalitarianism in politics, have to a high degree been supported by the belief that *I* am or *my* part is right, and right in an absolute sense, as a fact, and beyond doubt. Objectivism may foster inhuman attitudes between human beings.

The belief in the actuality of insight, knowledge, or true intuition in morals, religious normative dogmas, and ideological superstructures has, according to the Swedish and Danish value nihilists (Hägerström, Phalén, Alf Ross, to mention some whose works are in part available in world languages), contributed immensely to the mental and physical violence so prominent in the history of European countries in the last centuries (Lundstedt 1925; Ross 1953: 359).

I venture to suggest that the idea of normative knowledge would appear less repulsive if it could be combined with another idea that made its

use in support of religious, moral, and political fanaticism unlikely or impossible. This idea is that of difficulties of verification as an obstacle to an easy switch from truth to knowledge, from possibility to actuality.

Let us take the Golden Rule as an example. The belief that it either is true that you ought not to do against others what you do not wish others to do against you, or that it is false, and the belief that it is true, do not together make the Golden Rule a piece of knowledge. From the truth that Fermat's theorem either is true or is false, plus a belief that it is true, it does not follow that the theorem is a piece of knowledge. Perhaps it will never be known. In those cases in which verification is difficult or practically impossible, we are not entitled to proceed from the knowledge that p or non- p is true to the knowledge that p is true or that non- p is true.

Even in cases in which verification is not too difficult, we do not believe dogmatically and firmly in all our physical and mathematical beliefs as a consequence of our belief in an objective standard of mathematical and physical knowledge. We conceive that there may be a gap, wide or narrow, between our own beliefs and ultimate knowledge.

Applied to norms, this suggests that the road from knowledge that you are right or I am right to the knowledge that I am right might be as difficult or even more difficult to traverse than the corresponding one related to nonnormative knowledge. There may be practically unattainable requirements of ethical status, power of meditation, depth of understanding, integration of personality, freedom from prejudice, intensity of action and engagement, serene disinterestedness.

When the value nihilists suggest aversion to absolutism and dogmatism as a source of negative attitude toward value objectivists, an "unscholarly" motive may be said to be imputed to the former. Ross (1953: 172) suggests that such a motive operates in the camp of value objectivists: "What renders difficult the clarification of the problems to be discussed here is not only their inherent difficulty but also the unscholarly motives that, rising from the depths of the soul, make so many cling to a spiritualistic metaphysic and the edifying belief in a moral spiritual order of the world. Hence what we require to attain clarity is not only the intellectual ability to master onerous tasks, but also a certain quality of character: a consistent scientific purity, liberation from every craving for a metaphysical belief which at bottom is rooted in impotence and fear."

As regards the “belief in a moral spiritual order of the world,” it is important to note that only a subclass of such beliefs are beliefs in a moral spiritual order in the extended world. The ontology of Hägerström, and perhaps also that of Ross, is one according to which what is the case must be the case in a spatio-temporal world.⁷ The more refined value objectivists do not presuppose a narrow concept of what is the case and are therefore more difficult to argue against. What is the case may not always be the case somewhere. It is likely that an argumentation purported to be thoroughly “scholarly” (and therefore in the spirit of research) would have a more agnostic or sceptical conclusion than that of strong negations (it is *not* so that there is a moral order, it is *not* so that any norms are true, etc.).

Disagreement About Norms and How to Verify Norms Suggests That Verification Is Highly Problematic

There is not sufficient ground for rejecting the possibility of norms being true, but sufficient ground why we should reject the assertion that somebody actually at the moment possesses normative knowledge.

The main reason is, I think, the persistent disagreement among presumably normal, competent people who make an honest effort to understand one another’s ethical and other normative positions.

The disagreement seems to be less prominent in relation to fundamental norms than in relation to derived ones. It should also be noted that in political and other ideological structures, violent disagreement about what actually happens in the world plays a dominant part. Nevertheless, there is, in our time, sufficient disagreement concerning norms to reject them as expressions of knowledge.

A similar negative conclusion is warranted in relation to the many proposed ways of verifying norms, whether intuitional or otherwise. For expositions showing the difficulties of verifying value qualities (“tertiary qualities”) in a way similar to secondary qualities, the reader is referred to Ross’s article (1945).⁸ At present, there seems to be no way of verifying or confirming a basic norm that can compare with the methods of the sciences, even if we include such shaky fields as parapsychology.

On the other hand, basic presuppositions of the established sciences are in a position similar to that of basic norms. No matter how chaotic the

disagreement concerning ultimate foundations, though, many derived propositions and rules command near-universal adherence. If q is a consequence of p , and q is strongly confirmed, this cannot but make us trust p at least tentatively, even if the way of confirming q itself rests on the supposition of p being true. This may in part explain any lack of verification, and established knowledge of basic nonnormative assumptions is not taken as a sufficient reason for general scepticism.

A Planet with Hume's Argument Inverted

In every system of mortality which I have hitherto met with, I have always remarked that the author proceeds for some time in the ordinary way of reasoning, and establishes the being of God, or makes observations concerning human affairs; when of a sudden I am surprised to find, that instead of the usual copulations of propositions, *is*, and *is not*, I meet with no proposition that is not connected with an *ought*, or an *ought not*. This change is imperceptible; but is, however, of the last consequence. For as this *ought*, or *ought not*, expresses some new relation or affirmation, it is necessary that it could be observed and explained; and at the same time that a reason could be given for what seems altogether inconceivable, how this new relation can be a deduction from others, which are entirely different from it.

(Hume 1951: 469)

This famous passage introduces Hume's argument against rationalistic conceptions of norms. It presupposes a doctrine about what kind of reasoning is ordinary and why the ordinary should have any authority with us. If we start from a negation of that doctrine, the passage loses its force.

Let us suppose that there is a planet where physical laws are tremendously complicated, practically impenetrable, and further suppose that the morally intensively interested and physically uninterested inhabitants agree completely on all fundamental norms. These might then acquire the status of self-evident axioms and be contested only by cranks. There would be no embarrassing question of verification. Verification would be required only of derived statements and especially of norms derived in part by means of physical hypotheses.

On this planet where Dostoyevsky and others would have perhaps felt more at home, a David Hume might have stood up and warned his fellow philosophers, How do you manage to proceed from safe normative proposi-

tions to the highly doubtful physical ones? Scarcely by ordinary reasons! Physicalizing authors forget, he would say, to tell how they obtain their physics from a set of normative premises.

On this planet there would be physical nihilists proclaiming that physical statements are neither true nor false, and moreover, for a priori reasons, that they cannot possibly be true or false. The world of physical laws is an illusion, they might say, and the world of common sense, that is, that of values, is the only reality. In order to be true, a proposition must agree with reality, but there is no reality to agree with for a statement in the systems of physics.

A Planet with No Argument

Conditions on the imagined planet and on our own have in common a disparity between the extent and intensity of agreement on norms versus non-normative propositions. Now, let us imagine a third planet, where our conditions relative to nonnormative, especially physical, propositions and the conditions of the second planet relative to norms are both realized. Will there be any place for a Hume there? There would presumably be free passage from nonnormative to normative and vice versa, all in complete harmony with “natural reason,” and conditions of verification or confirmation would be agreed upon to the pleasure of both moralists and naturalists.

Basic Norms and Basic Nonnormative Assumptions of Science

It has often been pointed out that the methodology of testing the validity of basic norms lacks a chapter corresponding to that of observation in the methodology of nonnormative statements of science. The comparison is unimportant, because the chapter on observation does not touch on the foundations of science. The status of observation as a source of knowledge cannot itself be justified by observation. The psychology and physiology of sense perception are themselves based partly on observation and cannot be used to justify observation epistemologically without a *circulus in probando*. The status of observation as a source of knowledge seems in science to be postulated or to be taken as intuitively evident. That is, the justification of this status does not seem to be different from the kind of justification

needed in relation to norms, provided we have all found certain norms intuitively evident.

Comparing basic norms with basic nonnormative statements relied upon in science, we see that they have much in common from the point of view of methodology of testing: on the whole, “intuitions” are relied on.

If the basic methodological rules of science are formulated as norms—as they often are—the difficulties of testing will be similar to those in science. The question arises whether a proposition in science arrived at by means of such a rule should be called true or false, if basic norms are denied truth-value.

As regards the principle of induction, it is agreed that it cannot be justified by observation. Max Black and others prefer to speak of the principle as a policy, the policy of expecting certain things to happen rather than their opposites (Black 1954). It is often formulated as a norm. If this norm is negated and a very different one adopted, the content in textbooks of physics or history would have to be radically changed.

All this adds nothing to the reason for believing in the possibility of normative knowledge, but it eliminates certain misconceptions about non-normative knowledge. Nonnormative knowledge also has its problems or even paradoxes. Its basis is obscure.

The foregoing seems to support the contention that the distinction between norms and nonnorms in relation to truth-values is something upheld and justified by belief in what is or is not, that is, in what is the case, rather than by valid a priori reasons. In the strange worlds into which our world may develop, for all we know conditions may favor other beliefs. They are at the mercy of future experience.

In using the term *belief* I do not intend to convey that the change in standpoint toward norms and nonnorms would be irrational. The change may be justified by induction or any other kind of rational argument a posteriori that commands universal assent today.

Consensus omnium should not be taken, it is often said, as a reliable criterion of truth. On the whole, however, what actually is considered to constitute knowledge among researchers in a field is just those beliefs that are universally held by those who are considered to be experts. If there is much disagreement among experts about a proposition, it is not considered (safe) knowledge. Practical variation of conditions of agreement, whatever their

causes, changes our conception of what is real or objective, and the change may be in favor of normative or mixed normative–descriptive models of reality, away from the physical or other purely nonnormative models favored today among scientists.

A Posteriori Questions Leading Us to Empirical Research

Our conclusion from the foregoing is that arguments functioning in the debates concerning norms and truth-values as if they were a priori arguments, in part are not a priori, in part are a priori, but not decisive.

It is not the aim of this article to enlarge upon the a posteriori arguments. I should like, however, to emphasize that in many a posteriori considerations of general and abstract kinds, empirical research has been fruitful. It is methodologically sound to look for possibilities of such research relating to norms.

A task for empirical research of a nonsemantical kind is, just to take an example, to find out how scientists and others actually justify their assertions (whether normative or not) when confronted with repeated, persistent questions of *why* and *how*. Preliminary experiments suggest that the chains of arguments do not tend, in the long run, to end up with observation sentences (Naess 1937–38: 384). It seems that methods of verification by non-philosophers generally comprise both norms and descriptions as links in the argumentation chains. This has some bearing on the contention that there are no methods of verification of pure norms. There is no indication that the norms occurring in the links are all instrumental or otherwise different from basic or pure norms.

Another task of empirical research it is to study fluctuations in the conceptions of reality, especially the fluctuations in regard to the prestige of a space-time manifold as typical of what is real. Such studies would be relevant for our estimation of the sources of our intuitive certainty that it cannot be the case that something ought to be. If what is the case is always something in space and time, as, for example, Hägerström seems to presuppose, it will never be the case that something ought to be. The strong conviction that value nihilism is true may partly stem from belief in a kind of physicalist reality.

This does no more than hint at the kinds of a posteriori arguments that

lend themselves to empirical research with more or less established methods, or that ought to be studied in order to look for possibilities of empirical avenues of attack. There seems to be enough to do in this field for generations of researchers who are interested in philosophical reflections with empirical bearing.

Ultimate *Epoché*

Will empirical research give decisive results? Or, more generally, can a posteriori arguments be decisive? It is difficult to see how any set of arguments whatsoever can be decisive without its framers' already assuming rules of inference and basic descriptive assumptions. The "choice" at this initial stage of any argumentation will largely determine the force of empirical findings.

Thus, the above reasoning results in rejecting the decisive force of both a priori and a posteriori argumentation in answering the question of truth-value of basic norms. I cannot see any way leading to a rational decision. A suspension of judgment, an *epoché*, seems appropriate.

Gestalt Thinking and Buddhism

Impermanence

In the oldest forms of Buddhism, monks were reluctant to answer metaphysical questions. If answers were offered, they were expressed undogmatically: take it or leave it. Even if true, a philosophical opinion might be of little help, or even a hindrance on the Eightfold Path.

Permanence, even eternal being, is often asserted of substance (Descartes, Spinoza) and of some other types of metaphysical entities beyond or behind “appearance.” Gestalt ontology considers these entities to be *entia rationis*, abstract constructions created (by reason) to facilitate rational analysis.

The concrete structure may have a lower or higher degree of permanence. The structure of an ecosystem may show notable change during a century or practically none at all. It may show a short or long *half-life*, in the sense that this term is used in the theory of radioactivity. Abstract structures are timeless, but reason employs them for a short or long time.

The concrete contents of reality are shifting. Discontinuity and universal impermanence characterize the world of gestalts,¹ perhaps not quite in the sense of Buddhism, but in a closely related sense.

Anatmavada and Self-Realization

The “doctrine of no (permanent) Self” is essential to both Buddhism and gestalt thinking.

This article was written in 1985. It is being published here for the first time.

In my personal outline of a deep ecological philosophy (Ecosophy T), “Self-realization!” is the logically (derivationally) supreme norm, but it is not an eternal or permanent ‘Self’ that is postulated. When the formulation is made more precise, it is seen that the Self in question is a symbol of identification with an absolute maximum range of beings. Selves are frequently recurring entities, or “knots,” in the structure of contents, but they do not have the concreteness of contents! Ego, self, and Self are *entia rationis*.² The same applies to a term such as *self-realization*. This status as instruments for thinking, however, does not exclude such terms from appearing in important statements. “Only through one’s self-realization one can attain nirvana . . .,” says Masao Abe in his article (1985: 31) concerning Dōgen’s term *buddha nature* (*buddhata*).

Everything May Become Buddha

“Grass, tree, nations and lands, all without exception attain Buddhahood.” This is taken to be a motto in the Japanese Tendai tradition (Nara 1985: 1). Tentatively, I take “all without exception” to refer to gestalts, not to fragments or relata in abstract structures. Thus, it is not asserted that a tree defined solely by its primary or “objective” qualities may attain Buddhahood. Rather, I assert that attainment of Buddhahood is only permissible for gestalts, such as those that connect the tree with all qualities and attain semipermanence through recurring traits.

There are, of course, a variety of interpretations of “becoming the Buddha,” but some are closely related to the concepts of Self-realization through identification. The Buddhist compassion extended to all beings implies “seeing oneself in all things,” a process of identification. Without this, things appear foreign, *devoid of life*, and impossible as objects of compassion. If I have understood Abe correctly, Dōgen’s concern for elimination of the process of generation and extinction is central. The identification of human beings with animals, plants, and other natural objects rests on a common basic cosmic characteristic: generation and extinction.

There is a question of how wide a range of beings may be said meaningfully to realize themselves. Animals, yes; plants, yes; but including a wider range of things further dilutes the very concept of realization and

Self. There is a limit here, but it is not definite, and the options regarding how to trace it are many.

The similarity to certain forms of *māhāyana* consists primarily in the tendency to widen the range of “becoming Buddha” or “realize the Self” beyond what common sense in our culture seems able to digest. The meaningfulness of everything becoming Buddha is in part dependent on the disappearance in (certain forms of) *māhāyana* of *distinct* things. This leads us to the difficult problem of how to interpret the Buddhist *anatmavada*, the negation of the existence of selves.

Selves as Processes

Personal pronouns and all other forms of language referring to individuals and groups of individuals are used freely and in a standard way in fundamental Buddhist texts. Consider the following examples:

“Monks, do you not speak that which is known by yourselves, seen by yourselves, found by yourselves?”

“Yes, sir!”

“Good, monks! You, monks, have been instructed by me through this timeless doctrine which can be realized and verified, leads to the goal, and can be understood individually by the intelligent.”

(*Majjhima Nikaya*, I, 265)

Engineers lead water,
fletchers make arrows,
carpenters form the wood,
wise men master themselves.

(*Dhammapada*, verse 80)

In the sentence “wise men master themselves” the word *atta* is used (Sanskrit *ātman*). There is, in this passage and in others, no hesitation in proclaiming that wise men (*pandita*) have selves. The selves are tamed or mastered (*damayanti*), but not destroyed.

The famous sentences in the *Diamond Sutra* must, as I interpret the text, be understood in a way that does not make the use of personal pronouns and terms such as *self* questionable or even illegitimate. The individual selves are processes or aspects of processes, always changing, but always

showing an important, limited continuity and permanence. The words of *Samyutta Nikaya*, I, 135, are instructive:

Why do you then harp on the word “person”? Mara, you are starting from wrong premises. This is nothing but a lot of processes; no “person” is found here. For just as the word “carriage” is used when the parts are combined, so the word “person” is commonly used when the factors are present.

One may, as in this translation (which is Rune Johansson’s),³ render the word *satta* with “person,” but a more general term may also be used. What appears to be said is that no entities exist that do not have the character of processes.

To “realize oneself,” as I use the phrase, corresponds to some degree to the Buddhist expression “to follow the path.” Each must follow his or her own path, because of different experiences (see the quotation from *Majjhima Nikaya*), but the different paths, if followed far enough, lead to states that have something in common.

The ultimate goal in Buddhism is indicated by the term *nirvāna*. However interpreted, *nirvāna* cannot be understood in terms of Hindu metaphysics. The idea of a universal, absolute *Ātman* is foreign to Buddhism. As I use the expression “realizing the great Self,” it does not correspond to a Hindu idea of realizing the absolute *Ātman*. If I should choose a Sanskrit phrase for *self-realization* I might select “realizing *svamārga*,” “realizing one’s own way.” The “great Self” corresponds to the maximum deepening and extending of the *sva*⁴ through deepening and extending the process of identification. In any case, the great Self is an *entitia rationis*, not a concrete content or the set of all concrete contents—but it is still unclear if such a concept can even be defined without paradoxes.

Once the status of egos and autonomous selves is downplayed, there is little left of the foundation for making sharp distinctions between anything. The *warning* not to take individuality too seriously or literally is forcefully expressed in the *Diamond Sutra*:

Subhuti, what do you think? Let no one say the Tathagata cherishes the idea: I must liberate all living beings. Allow no such thought, Subhuti. Wherefore? Because in reality there are no living beings to be liberated by the Tathagata. If there were living beings for the Tathagata to liberate, he would partake in the idea of selfhood, personality entity, and separate individuality.

The special wording of this passage should also not be taken literally. The idea of liberation has validity, but one must not absolutize the distinctions and believe in substantial existence.⁵

Transcending Subject-Object Dualism

The belief and acceptance that all whole beings can attain Buddhahood depend upon the rejection of subject-object dualism. That is, one must abandon the sentiment that there is always and always must be an ego involved in experience. Appeal to spontaneity, perhaps especially spontaneous experience in nature, is favorable to a detached view of subject-object relations. The nondualism in Buddhism is sometimes expressed verbally by saying that all beings are one, or that each being is one with all other beings. Such a formula must not be taken in the counterintuitive sense that, for example, I cannot be cold and hungry and somebody else warm and satisfied. The formula does not imply rejection of personal pronouns or any psychology of the ego and self.

It is an interesting problem to formulate clearly the views that have rejection of subject-object dualism as a common characteristic. Whatever way we formulate the nondualism, adherents of deep ecology tend to feel sympathy with views such as the following, expressed by Yasuaki Nara:

[I]n Dōgen, through the negation of the egocentric self, whole being, including man, animal, mountains, rivers, grasses, trees etc., is one with him, making both nature and himself encompassed within the world of the Buddha.

(Nara 1985: 2)

Referring to a poem by the poet So-to-ba “in which the sound of the mountain river revealed reality and the poet had *satori* in listening to it,” Dōgen emphasizes the oneness of So-to-ba and the sound of the river by asking whether it was So-to-ba who had *satori* or the river (ibid., p. 4).

As I see it, a happening refers to a whole constellation or gestalt of relations. “Satori!” might well be an expression of a kind of happening. In that case, it is not evident that one should be able to sort out a subject “having” satori, or an object eliciting satori and revealing reality to the subject. The satori as a content is one, and only an analysis of abstract structure leads to definite conceptions of parts of the whole.

The *words* of Buddhaghosa can be used in proclaiming the reality of gestalts rather than subjects and objects:

For suffering is but no sufferer,
not the doer but certainly the deed is found
peace is but not the appeased one,
the way is but the walker is not found.
(*Visuddhimagga*, XVI, 90)

The term *suffering* (*dukkham*) may be a good name for a class of gestalts. Each member of the class has a structure comprising subject, object, and a medium. The term *sufferer* (*dukkhita*) suggests a narrower connotation, pointing merely to a subject who suffers. Similar reflections may be made concerning the other pairs of opposites in the quoted text.

The indefiniteness and plurality of conceptual analysis are clearly indicated in what Yasuaki Nara says about another poem, one by Matsuo Basho:

Old pond
A frog jumps in
The sound of water

“Here Basho and surroundings are interfused; Basho, the frog, and the pond are one world and the one who jumps into the water may be a frog or Basho himself; the sound is of the water or of the frog or even of Basho” (Nara 1985: 5).

The poem is from the point of view of gestalt thinking a high-level expression of a concrete content. Conceptual analysis may split it up, but it has gestalt status, and the splitting will be more or less arbitrary. This applies even to the subject-object distinction. It may or may not apply as a significant abstract structure attributable to the gestalt.

Western historians of world literature tend to create conceptual analyses that stress the *internal* life of the mind. A Zen Buddhist poem “about” the branches of a tree might in this tradition be explained as follows: The poem tells about the sadness expressed by these branches, but in reality the poem expresses the sadness of the poet. The poetical style requires a projection of personal states of consciousness into objects of the external world. This form of analysis makes Zen poetry and ontology into a subclass of Western poetry and ontology. Yasuaki Nara proposes a translation that is

not essentially different and offers the following to the above analysis: “This poem is *not* a mere description of the scene communicating the quiet atmosphere but the expression of the poet himself, absorbed in the quietude” (ibid., p. 5).

Nara resorts, in explaining the poem, to the distinction between the poet and the scene, a distinction similar to that between man and environment in the shallow ecology movement.

What the both-answer can do in these matters is to delay, or hold back, the introduction of the subject-object distinction by admitting a diversity and richness of ontologically homogeneous traits (rather than “properties”) of a constellation. Primary, secondary, and tertiary traits are completely on par. The secondary and tertiary are not in need of a subject, a mind, a consciousness in the form of a container with subjective ponds, frogs, trees, and water inside it. The concept of “things in themselves” is held back because we do not find contradiction between dissimilar utterances about “the same thing.” (“Things with properties” are described in terms of “fields”—comparable to what occurs in physics.)

The both-answer has, of course, a rather limited function; the same holds for the notion of “concrete content” as contrasted with “abstract structure.” As starting points of reflection about “things,” however, they liberate us from certain prejudices.

Things in Themselves and Values in Themselves: “All Things Have Value”

There are some complications worth mentioning at this juncture. One must distinguish subject-object dualism from subject-object distinctions in general. The term *dualism* is used when the distinction is said to be fundamental, absolute, and pervasive. Dualism is accepted in the theory of duplication and in the theory that things in themselves do not have qualities. Everything we experience has such qualities. Rejecting them means establishing duplicate things inside the mind.

The outstanding dualist of Western philosophy is René Descartes. Many of the contemporary efforts to avoid the paradoxes and counterintuitive consequences of dualism are conceived in terms of anti-Cartesianism. It is not sheerly coincidental that Descartes is also the main proponent of

the view that animals are insensitive machines and nature has value only as a resource for human beings. However, I shall not attempt to explore connections between dualism and these historically significant views.

The insistence that there is nothing, no substance, “behind” the concrete contents corresponds to the Buddhist conception of *sarvam tathatvam*, “all is such as it is.” However, the conception of a world of concrete contents and fields rather than things in themselves may seem to undermine our concern for individual beings—animals and plants—and for abstract entities such as species. This need not be so. Spontaneous experience is not sense experience. It is experience of more or less stable things and processes of “the world we live in” (*Lebenswelt* in the terminology of philosophical phenomenology). When we see an orange we see a thing, not a patch of yellow or orange or greenish color. When meeting an animal, we meet in our spontaneous experience something enduring and self-propelled. The essential aspect of the ontology of contents is not a negation of enduring beings, but of the omnipresence of the “we” or “I” and the duplication in external and internal worlds.

These words are meant to introduce my comments to Yasuaki Nara’s interpretation of the Japanese notion *inochi* (life). He thinks it slowly came to refer to the intrinsic value of all beings. “Gradually, the Buddhist precept of *not-killing* has come to be understood not only as not taking life of animals, but also not taking *inochi* of all things. Sometimes it has further been said that *not-killing* is to let *inochi* live” (Nara 1985: 7).

The notion of intrinsic value as some form of life in a broad sense has important consequences. In some countries, the deep ecology movement is closely allied to lifestyles that are, in part, characterized by careful and respectful handling of things more or less in general, not only of sentient beings, not only of living things in the sense of organisms. There is remorse for taking their *inochi*.

The Japanese custom of *kuyo* (memorial service) must be mentioned here.

On a day sometime in Autumn, eel-dealers, restaurant managers and some ordinary people representing the general customers gather together to have a religious service. A small altar is constructed and one or more priests chant Buddhist sutras to the eels who were killed and eaten by us to nourish our

lives. The Japanese do not exactly believe in the existence of a soul of an eel. The implication of the ceremony lies rather in the complex feelings of remorse for taking their lives and *inochi*, of thanks, and of soothing their souls, if any. . . . In the Edo period, the housewife and daughters of each home were supposed to do *kuyo* for the used or broken needles with a sense of regret for their lost *inochi*, thanks, and also with prayers for the enhancement of their sewing talents. Since the Meiji period, the needle-*kuyo* has come to be observed by some temples or Shinto shrines collectively annually on February 18. . . .

Some medical doctors and nurses sometimes join, bringing the needles used for injections. *Kuyo* is also done for old clocks, dolls, chopsticks, spectacles, tea-whisks, etc. To sum up, the traditional view of nature in Japan first of all does not make a clear distinction between man, animals, and things. Though the individuality of each exists, all are felt to be part of the one world of the Buddha, each revealing its value.

(Ibid., pp. 9–10)

This horizontal or antihierarchical way of feeling things is gained by using the notion of concrete contents as a starting point. Or, to be more precise, the kind of philosophy I think comes closest to truth and that I feel at home with supports this kind of horizontality, and the notion of concrete contents facilitates its formulation.

If we think of some of the cruelest parasites, inflicting slow, painful death on their victims, it is difficult to invest them with any sort of positive intrinsic value. That analysis applies even more strongly to chemical and other weapons—but they certainly are “things” and therefore seem to be eligible for *kuyo*.

In short, what about the “problem of evil” in relation to the concept of intrinsic value of all things? Clearly this concept is as vulnerable as any other that tries to attach uniform positive value of some kind to all that is felt to be real (*sattva*). There is a need for clarification of the meaning of the intrinsic value conception, but I cannot go into the matter here.

The *inochi* and *kuyo* phenomena are primarily cultural in a general sense, not philosophical, but they furnish irreplaceable and invaluable raw material for philosophical reflection. In many Western countries, environmental struggle involves direct actions and violent confrontation. The norms of nonviolent group conflict as worked out by Gandhi and others ex-

METAPHYSICS, MORALS, AND GESTALT ONTOLOGY

clude violence not only against the opponents, but also against their machinery and other equipment that, from a direct causal point of view, destroy life and life conditions on a vast scale. The norms against so-called sabotage involving such equipment are based on deep attitudes that express themselves in cultural phenomena such as *inochi* and *kuyo*.⁶

Kierkegaard and the Values of Education

Kierkegaard's *Concluding Unscientific Postscript* can be used in a more or less futile effort to construct a total philosophy of Kierkegaard, or it can be taken at face value as an independent writing covering a great variety of subjects. The latter use is the more fruitful for those concerned with the crisis of higher educational institutions, such as universities, in affluent societies. If we take it as a completely independent work by a seeker and humorist, Johannes Climacus, we may interpret its key terms (*the ethical, inwardness, passion, involvement, subjectivity*, and so on) solely in their context within one particular text. It turns out that its importance, thus considered, is much broader and its application much wider than if key terms are interpreted in the light of what, for example, is said in *Either-Or*.

There are in the *Postscript* at least a dozen subjects with a bearing on the educational crisis.

Against Pretentious and Premature Systems

The delightful anti-Hegelian sayings of Johannes Climacus are today applicable to every pretentious explicit or implicit systematization covering controversial matters. They hit the belief in any scientific worldview based on (normative, decision-making) observational methodology. Such views are systems, and the question "How do they start?" is relevant. How does the system begin with the immediate? That is to say, does it begin with it immediately? Textbooks used in schools and universities propagate special

points of view in an authoritarian way. The young are asked to kneel down before nationalist, theological, historical, "scientific" dogmas and myths. Their own sources of myth-building and belief are ignored or made fun of.

The system-building most dangerous to the inner, individual sources of belief, including valuation, is today the interpretations provided by popularizers of science and by "experts" in administration. We need a neo-Duhemian stress on the difference between more or less certain and indubitable results of scientific or technical research, on the one hand, and interpretations and interpolations, on the other. The latter can exhibit vast differences in direction, but owing to ideological and other idiosyncrasies of teachers and parents, the young are stuffed with one interpretation, to the accompaniment of a negative inducement to allow their imaginations to play with other possibilities. Consequently, the very sources of creative personal belief are apt to dry up, with resulting loss of individuality and interest in spiritual matters. The vast textbook systematizations foster the illusion of a preexisting world common to all individuals in which they all live, one that is known in all important respects. We need to stress a pluralism of worldviews, of historical interpretations, of views on human existence. The unspoiled young feel that what is already there, preexisting and unchangeable for the individual living now, is only a skeleton of a world, an abstract structure, a set of invariances, without color and individuality. It is up to them to shape and give color to the world of today and tomorrow.

It is the choices of each individual, the process of finding himself, that gradually illuminates that particular world he is living in. Kierkegaard teaches us that there is a source of inner life that, if not clogged, generates values and sets of value priorities, that is, in short, an inwardness; and that truth in the abstract, as mere agreement with external observation, has no place for the individual if not related to that inwardness. In our time we stress the difference between results that can be recorded and stored in a machine, and a result incorporated in the personal worldview of an individual. The aim of the educator cannot be to multiply the former, but to bring about the latter.

Lack of space unfortunately precludes extensive quoting from the *Unscientific Postscript*; I can only invite readers to see for themselves how the critical remarks on Hegel's system and on systems in general are admirably suited to contemporary textbook authoritarianism and intolerance toward pluralism.

Correct Versus Deep Choices

The *Unscientific Postscript* contains a number of unsurpassed maxims stressing the importance of making personal choices. What counts, according to Johannes, is the seriousness, pathos, energy, genuineness, enthusiasm, and depth of choice. A choice may be taken as deeper the more it touches the system of attitudes as a whole, that is, the more radical or fundamental it is. Every deep choice creates a discontinuity; the individual develops into something different from what he was before, and something more self-made, autonomous. Only through such choices can the youngster develop into a strong personality. Only if he is able to “go into himself,” concentrate and listen to more or less immature impulses, and have the courage to follow them, only then can the growth of personality withstand the external pressures of parents and teachers trying directly to influence choice. Kierkegaard stresses this “consolation of personality” through personal choices. The ability to choose is itself a function of success in choosing—not success in the external sense of doing the right thing (socially) or believing the truth (scientifically or theologically), but success in overcoming compulsion from the outside or inside.

In higher education, there are choices to be made: what to learn, how to learn, how much to learn, how to use free time, how to establish genuine personal relations—and which kinds of relations—with fellow students and teachers. In principle, the choices must be made every day: there is no automatic transfer of decisions from day to day. These choices are classifiable as correct or incorrect only at superficial levels. The deeper choices have a purely personal relation, an individual component: is the chooser in truth?

To Hold True Opinions and to “Be in Truth”

Kierkegaard does not belittle the importance of facts and factual knowledge. On the contrary, the inner tension of the Christian believer can only develop if he takes the facts of historical and other sciences seriously, for only then can the paradoxical character of belief make an impact on him. Kierkegaard’s maxim, that truth is subjectivity, has the function of stressing the importance of the relation of the individual to what he believes is

true. The individual can be in truth or be in untruth in relation to propositions that have personal relevance. If the personally relevant factor of objective truth has been contemplated and chosen, the individual is in truth: where there is social pressure, there is untruth. In moments of choice the individual is alone. Through the artistic use of paradoxical terminology Kierkegaard has provided us with a rich store of expressions stressing the personal aspect of knowing.

Applied to institutions of higher education, this means that they serve depersonalization, uniformity, indifference, “other-directedness,” if they limit their concern to teaching truths (which are in any case mostly mere conjectures), neglecting the individual’s own relation to truths. The authority of Kierkegaard is sometimes used to belittle scientific research and objectivity. Seen another way, however, the researcher tries to be intellectually honest and open-minded in his choices, and the dedicated researcher requires his own kind of endurance and faithfulness as he proceeds (like the historians of the Bible) along the infinite “road of approximations.” Research, therefore, is one of the professions admirably adapted to test inwardness and ethical stamina. Actually, many youngsters have a clearer view of the scientific attitude than many teachers. By giving them suitable personally (but not necessarily socially) relevant tasks, we can maintain their respect for unending research (but not necessarily for the results of research).

The Ethical and the Inward

The neglect of *Unscientific Postscript* as a coherent, self-sufficient unit of thinking has negatively affected the interpretation of the term *the ethical* in that work. Researchers have linked this term with specific moral doctrines—for example, those of Assessor Wilhelm in *Either-Or*—or with topics that are centrally important in other writings by Kierkegaard but not in the thinking of Johannes Climacus, the alleged author of *Unscientific Postscript*. In that work, *the ethical* is mainly another term for “the genuine,” “the inward,” and there is no propagation whatsoever of any definite morality, for example, that of duty.

Applied to educational philosophy this means the limitation of moralizing to stressing the duty of the person to choose in all seriousness, and to

follow a decision faithfully, working out all the consequences of his or her choice. The educator can only help the individual with information relevant to the preparation of the choice and the derivation of consequences. Any indoctrination or direct influence, especially as regards norm systems and theological, moral or political propositions, is poison; either it destroys or undermines the growing individual's ability to consolidate a personality, or it supports negativism: the uncritical acceptance of views in opposition to those of authoritarian teachers.

The Illusion of Greatness and the Unimportance of Results

Unscientific Postscript contains a rich variety of maxims stressing that an individual should not concern himself or herself with success, with the external results of choices, efforts, or acts, because they are only indirect at the moment of choice. The only concern is that of being ethical—reaching a high level of inwardness—being in truth. It is clear that to obtain a high score here does not require intellectual ability, social position, or smartness. For the educational philosophy of higher educational institutions, the consequence is to minimize the stress on the external success of the pupils, on competence measured by objective tenability of views and effectiveness in handling “problems.” There are, of course, kinds of training (for example, that of a future surgeon) in which external criteria are all-important, but no institute of learning can, or should, limit itself to such training. In all training, including that of mathematicians, the stress on success can safely be minimized in relation to the importance of the personal relations. For example, rather than “the mathematical,” we can emphasize mathematical contemplation and fantasy in the value of individual mathematical exploration. We have our machines to store results, and to carry out tasks with the sole view of obtaining results.

With the increasing centralization and trend toward uniformity of world culture, and with the accompanying increase in the comparability of results, the attainments and success of the average individual are less and less conspicuous. Young boys or girls are confronted with people who have achieved a level that it is utterly improbable that they themselves can reach. The constantly recurring implicit and sometimes even explicit rating of individual attainments based on external criteria makes it more diffi-

cult than ever for the average youngster to feel important, to feel what Kierkegaard stresses: that he or she is something unique, worthy of development and care. Insofar as education favors inwardness, the rich and intensive inner life, exposure to superior scholastic talent does not endanger it.

Indirect Communication

Nothing essential can be communicated from one individual to another, according to *Concluding Unscientific Postscript*. Insofar as the maxims on inwardness are essential to the welfare of the individual, they cannot be communicated directly. Ordinary, informatory language is direct; it does not elicit or free the inner forces. Therefore, the teaching of Johannes Climacus, if he does teach, cannot be made part of any curriculum. The philosophy of inwardness, if there is any, cannot itself be made the subject of any textbook or any educational indoctrination. The spirit of that philosophy can only manifest itself in the personal relation between teacher and student.

This is not the place to map out specific applications of a philosophy of education based in part on the above interpretation of the maxims of *Unscientific Postscript*. There is, of course, scope for various interpretations of those maxims, and application cannot be immediate but must carefully take account of how each contemporary educational institution is operating.

Of the various objections that might be made by leaders of such institutions, there is at least one that deserves to be mentioned here: it is said that the institutions must adapt the young to the present complex, technological society. In this society it is the external, the smoothly functioning, and the successful that count, not richness, variety, and intensity of inner life.

The answer to this must be that such a smooth society turns things upside down. Such social smoothness is of lower priority than community, and personal togetherness with fellow beings. For in being together, smoothness and external success do not count, and there are no technicalities to adapt to. Further, even the norms of being together have a lower priority than those of the inner life of each individual; that inwardness is the ultimate reference for any norm whatsoever. Thus, the higher educational institutions must make it easier for the young to remain unadapted, or imperfectly adapted. Otherwise, they contribute to the life of the big, impersonal, affluent society, with its external richness and inner poverty.

The Principle of Intensity

If you fill your bathtub half full with water at 40° C and then after a moment's hesitation fill it completely, the temperature does not increase to 80°. Forty plus forty is eighty, but because *temperature is an intensity*, more water of 40° C does not increase the temperature. The rule of addition does not apply. One person in a room is suffering from a toothache of a certain intensity. Then another person enters the room with the same kind of suffering. This does not automatically double the felt intensity of any suffering.

In Hiroshima on August 6, 1945, after 9 A.M. a great number of people and animals suffered intensely. We may safely infer that some of them suffered prolonged pain in the terrible realm of maximum intensity. The same day, thousands of miles away, some other people presumably also experienced extreme suffering. With thousands of millions of people on our planet, there are presumably always people in a state of extreme felt suffering. The larger the population, the greater the “statistical” suffering, or *cases* of extreme suffering. There need not, however, be an increase in *felt* suffering. It is important to emphasize the adjective *felt*, because as criteria of pain and suffering we often rely on “objective” indicators, rather than feelings. I add the term *suffering*, because *pain* is sometimes used only for physical pain. On the other hand, *suffering* is sometimes used without im-

The original version of this paper dates back to the late 1940s; in the early 1990s Naess added the discussion on life quality. A paper by the same title, with much of the same material (but based on an earlier draft that does not include the life quality discussion), appears as “The Principle of Intensity” in *The Journal of Value Inquiry* (Dordrecht, Netherlands: Kluwer Academic Publishers) 33 (1999): 5–9.

plied felt pain, as in the expression “suffering a lack of x ,” vitamin B₁₂, for example.

People in Hiroshima wandered around with eyes intact but with the skin of their faces hanging down in a terrifying way. Some of them seemed to be in a state of confusion rather than a state of excruciating pain. If we look at pictures of 100 people in famine districts, our judgment about relative intensities of suffering tends to confuse the awfulness of what we see with the felt pain. Rescuers with limited supplies are in a difficult position. Who has priority?

Thinking of Hiroshima we might say, “What a stupendous amount of pain!” but strictly speaking, the number of people afflicted is irrelevant when speaking of felt pain. What is pain that is *not* felt? Hiroshima was a catastrophe of staggering dimension, but the dimension is not an intensity. It may *cause* variation of intensities but is in itself irrelevant.

During the Nazi regime more than a hundred thousand people were severely tortured. Some torturers were “scientific,” trying to use only a sufficient dose to get hold of all the information the victim could be *rationally* supposed to possess. Others started with extreme torture immediately and continued indefinitely, trying to cause the most insufferable pain imaginable. If the tortured started to offer information, their suffering tended to increase owing to their terrible guilt feelings. Unfortunately, the situation nearly always was such that no one could rescue the victims even when the exact location of the torture chambers was known.

At a given moment one may ask, What is the status of felt pain on the planet? With so many people in so many precarious situations, the answer is plain: there is always too much felt pain and suffering.

The next question to be answered is, What can be done to reduce felt suffering, given limited power and opportunity to do so? That is, what can be done by individuals and by institutions? What sort of collective action is feasible? This leads immediately to the question of priorities. If person *A* is obviously in extreme pain and *B* is only in moderate pain, and we have equal opportunity significantly to reduce or even eliminate the pain of one and only one of them, philosophical ethics tell us, or at least some of us, to act on behalf of *A*. What about a situation, though, in which person *A* suffers extreme pain; hundreds of other people, group *B*, suffer moderate

pain; and 10,000, group C, suffer pain of slight intensity? Do numbers count?

Here the maxim “Reduce maximally the pain and suffering of a maximum number of people” is relevant, but of little help. Numbers do count, and for good reasons. It affects us more strongly to hear about a catastrophe like that of the *Titanic* in which at least 1,500 people perished than to learn about a little boat capsizing, killing the two people in it. If, as rescuers, we have to choose, we normally view sheer numbers as relevant.

What if the choice is between saving *one* person from extreme suffering and a *thousand* from moderate pain, assuming that the thousand do not interact with one another as people often do on a boat? My answer is that we should try to relieve the person who experiences extreme suffering, but I have to admit to a feeling of absurdity when I increase the numbers and decrease the difference between the intensities of suffering felt. Suppose we are in a region of starvation, and suppose the many suffering moderately could easily move into situations of greater suffering. I feel we should then help the many who suffer moderately, and explain the situation to the one person suffering much more. I expect he would say something like, Yes, I see your dilemma. I am glad you have decided to help the others.

One thing that unavoidably crosses my mind is that we should consider consequences of more remote kinds in addition to the immediate decrease or elimination of pain. If we are able to help a vast number of people by a decision or action, this may have more beneficial and lasting effects, also in terms of expected new pains, than if we are able to eliminate the severe pain of a single person. I expect that the situation is fluid and that decisive help to a group of 1,000 sufferers or potential sufferers could seriously decrease the possibility that many of them, or their children, would reach a high level of suffering in the future. Although it is often most reasonable, in practice, to let the quantity of persons affected influence our intervention strategy—the *principle* of intensity is not diminished.

No norm is isolated in practice. In “real life” any norm is part of a wide field of norms that interact. Norm conflicts are normal. Moreover, the uncertainty of appraisal enters the picture: under what circumstances are we competent to decide whether a person is experiencing such and such a level of intensity of suffering? Furthermore, whether we like it or not, in prac-

tice we generally think about whether a person deserves to be helped. Age is also a factor. For example, the slight but evident suffering of small children may count more than that of their parents. Babies dying of hunger may suffer very little or, according to physicians, be beyond suffering. They tend to be treated because of the anguish of their parents. Furthermore, dignity is also a factor. Many people *suffer* indignities and wish to be relieved of them more than any suffering diagnosed by a physician.

The strong norm to relieve fellow human beings in situations of intense suffering has sometimes resulted in a rescue of someone who seriously and insistently asks to be left alone. A well-known example is that of old Mr. Fukai. After the explosion of the atomic bomb on Hiroshima, only his head appeared above the rubble of his home. He was suffering intensely. A warmhearted person saw him and started to pull him out because fires would otherwise consume him. But Mr. Fukai, as polite that day as he was on all other days, begged not to be removed from his own home. Despite his plea, he was carried away from his burning home. The warmhearted person waded into the nearby river in order to be away from the heat. Mr. Fukai was able to escape from the refuge his rescuers had put him in. He was grabbed again, and he escaped again. He ran in the direction of his burning home, where he presumably died in the fire. Did Mr. Fukai escape a suffering greater than he would have experienced if he had been "rescued"? I would say he probably did. It is difficult for me to see the justification of grabbing Mr. Fukai, even if his behavior might be interpreted as an expression of insanity in a popular sense of that word. An individual should largely be accorded the competence to estimate his or her own suffering, and persistent mental suffering should be judged as important as physical suffering.

An old colleague complained to me that his doctor concentrated on fighting his deadly illness, neglecting the less dangerous, but much more debilitating ones. He did not mind dying, but while he lived, he was interested in the quality of his life. He neglected the main orders of the doctor and died sooner than if he had subjected his will to that of the doctor. This brings us to the question of whether there are important exceptions to the rule that intense suffering should, if possible, be relieved; whether the wish of the sufferer about how to alleviate his own suffering should be respected. Terminally ill patients who find their lives completely meaningless and

who suffer both from this mental condition and from physical pain are, in spite of persistent requests to be given assistance in dying, in many countries denied this assistance. I expect such resistance to disappear gradually, but a feeling of the sacredness, not only of life, but of staying alive, plays a role here.

Finally, consider an example of a situation involving a form of extreme mental suffering that is frequently overlooked by social institutions. When Norway was liberated from the Nazi occupiers in May 1945, I had the opportunity to locate a group of people likely to be in a situation of extreme mental anguish. When the gate of the huge Nazi concentration camp near Oslo was supposed to be opened, parents streamed to the gate to meet their imprisoned sons. Some of the young men, however, did not show up. For the parents, the thought was realistic that their sons had been killed, or even tortured to death, by the Gestapo, but they hoped frantically that their sons were alive somewhere. It was a meager help, but not insignificant, to investigate the cases and offer certain evidence to the parents about what had happened to these young men. They insisted on getting details. They woke up in the middle of the night considering all the dreadful possibilities. It had a devastating influence, and those engaged in jobs had problems; some could not continue with their work. Of the young men who had not been tortured to death, some had died of "exposure," for example, in extremely cold cells; others had managed to use poison pills to avoid imminent torture. It is not surprising that this group of parents could not reckon with help from ordinary social institutions, including the Red Cross, which had much work to do of a more ordinary kind. More was done to prosecute and imprison the quislings, those who directly or indirectly assisted the occupying Nazi power, than to assist the victims.

In short, not enough is done to save people in a state of intense pain and suffering. We forget that there is, in a sense, never a greater reduction in *felt* pain than when an individual is saved from extreme suffering, and that "statistical suffering," the mere numbers, does not always matter. The false *quantification* of felt suffering tends to quell efforts to reach the victims.

In countries where torture is used regularly and ruthlessly, people who fight year after year against those in power daily face the prospect of being tortured themselves. Very little, in my opinion, is done to organize secret

routes out of these countries, so that the victims themselves can get out on short notice—and back in when the situation is more favorable. Such routes played an important role during the Nazi occupation of many European states. Thousands of people were engaged in saving others from continued torture. Governments today, however, take few risks to put outside pressure on dictators in spite of the improbability that the dictators will harm the rich, industrial states. It is an international task to support human rights activists in every way, including direct, nonviolent actions.

There are organizations specializing in helping people who have been tortured to restore them to normal life, but they receive little publicity. This is probably because most people avoid the thought that at every moment of their lives people are being tortured somewhere in the world. Pictures of land mines and their victims helped to secure agreements to stop the use of land mines. There is an understandable reluctance to publish drawings of the physical effects of torture and a reluctance to interview people in psychiatric care who are unable to resume normal life. From insistence on inspecting the possible manufacture of biological weapons, we must proceed to insistence on inspecting the treatment of prisoners.

In general, there is a tendency to neglect “quality of life” in favor of quantity of objects and services, which supposedly secures quality. Suggestibility is a formidable force, and it is easy to increase to some extent the quality of life by noticing every day the great number of *means* available. “See what I *have* to secure happiness and avoid depression! I have everything!” Every *thing*, yes, but we all agree that it is unrealistic to believe that a steady stream of more and new things may or must increase an intensity called quality of life.

At a deeper level, however, there is a tendency to help where we believe we *see* what is most needed. The “needy” are conceived to be those *lacking* something, and they themselves naturally express their wants in those terms. What *is* needed, more than anything else, is to relieve intense and prolonged felt suffering. The reduction in the material standard of living in the richest countries of the world does not help suffering in the poorest if the decrease of consumption in the rich is not combined with an increase in the poorest. What complicates matters, however, is the tendency to discount the suffering of future generations of human and other life-forms.

The increase of consumption of the poorest of this generation may be of a kind that will decrease the quality of life of future generations.

The discussion of the principle of intensity applied to felt suffering has brought us a long way. We face the question "To what extent do policies in the poorest countries focus on felt suffering and to what extent do they focus on acquiring things that symbolize an increase in material standard of living?" To what extent do the rich countries have responsibility for making the poor countries unduly focus on the things that can be added rather than on what does not follow from the law of addition?

Let my closing words be: Let us not forget that feelings are facts, but not like any fact; they are intensities. They do not obey certain rules of addition. There are feelings so terrible that rescue deserves a higher priority. Awareness at some moment that someone is being tortured spoils that moment. It is to be hoped, however, that more people respond with the question "Is there anything I can do?"

We Still Do Not Know That Norms Cannot Be True or False: A Reply to Dag Österberg

Argumentation 1

Premise 1: Norms are not propositions.

Premise 2: All denotata of the predicates “true” and “false” in philosophical literature have been, until now, propositions.

Conclusion: Only propositions can be true or false according to philosophical concepts of truth and of norms.

This conclusion I do not think tenable because whether norms can be true or false depends rather on connotation than on denotation of concepts of truth. Until certain discoveries were made, denotata of “carnivorous” in zoological literature were always animals. It has been fruitful, however, to let the connotation of “carnivorous” be free from references to the distinction between animals and plants. The appearance of plants as denotata did not necessitate redefinitions.

Österberg has interpreted me to mean that contemporary definitions (and therefore connotations?) of truth are such that “true norm” and “true but not a proposition” are contradictory. However, only *some* definitions of truth contain a clause that only propositions can be true, and I see no reason

This article was reprinted with permission from *Theoria: A Swedish Journal of Philosophy* 28 (1962): 205–09. The article by Dag Österberg shows the necessity of clearer presentation of certain argumentations.

automatically to take them as authoritative. There are dozens of definitions or statements closely resembling definitions without such a clause. Thus, Bertrand Russell says: “What an asserted sentence expresses is a *belief*: what makes it true or false is a *fact*, which is in general distinct from the belief” (1948: 111–12) and “My definition of truth is that a belief is true when it corresponds to a fact” (1948: 18).

The conception of an absolute, correct concept of truth is utterly foreign to me. So-called definitions of truth must, to be adequate, have certain relationships to actual use, but occurrence analysis or other scientifically satisfactory techniques of studying actual use cannot yield (by induction or otherwise) just one definite, so-called definition. The definitions are conceptual constructs with complicated and indirect relations to the observational data.

If we have good reasons for believing that a certain norm is true (or false)—using one of the definitions of truth that do not limit truths to propositions—consideration of fruitfulness may lead us to abandon those definitions (or, more general, conceptual constructs) that make it impossible for norms to be true. As stated explicitly in my article “Do we know that basic norms cannot be true or false?” argumentation 1 concerns “the denotata, not connotation of truth and falsity.”

Let us briefly consider another argumentation.

Argumentation 1a

Premise 1: Norms are not propositions.

Premise 2: All definitions of truth in philosophical literature until now have included a stipulation that only propositions can be true or false.

Conclusion: Only propositions can be true or false.

Even this conclusion seems to me unwarranted. One might say “According to every definition in philosophical literature until now, only propositions can be true or false,” but formulations of definitions in philosophy are implementations of certain *tasks*, for example, in relation to explication or analysis of actual use of the terms *true* and *false* in certain texts. Definitions are

considered more or less good, and there are more or less generally accepted rules for when to discard a definition and adopt a new one. In the case of definitions of truth and falsity, the core of the definitions is not a stipulation that only propositions may be true or false, but expressions such as “agreement with reality,” “coherence,” and so on.

Österberg would be right in maintaining that my criticism of the conclusions in argumentations 1 and 1a is commonplace or trivial. If, however, we consider the actual situation, namely that some norms *are*, by some philosophers and many nonphilosophers, claimed to be true or false, the insufficiency of arguments based on definitions or on denotata in philosophical literature should be pointed out. Those who maintain that they know that norms cannot be true or false because of certain definitions, should state their reasons for thinking that those who do *not* deny the possibility of true norms should adopt a definition of truth such that norms cannot be true or false.

Österberg agrees that it can be true that we ought to do X if it can be the case that we ought to do X, but he adds that “it is valueless to us until we know what is meant by ‘something being the case’.” “*Criteria* must be given,” says Österberg, and he thinks it a “sin of omission” that I do not offer criteria (Österberg 1962).

Now, formulations of general criteria of something being the case are scarcely helpful, perhaps because “to be the case” is something very fundamental and very simple. Phenomenologists have offered masterly and vivid accounts of what is experienced when judging something to be the case. Especially the descriptions of self-evidence, of insight that such and such evidently must be the case, are impressive pieces of literature. There is, however, something unsatisfactory in the phenomenological accounts if addressed toward people who are uncertain about which criteria of “being the case” are good criteria. Either one’s intuitions fit the descriptions or one has no reason to accept them. Even, however, if it may be unfruitful to search for *general* criteria that something is the case, particular criteria might be useful. I consider it to be the case that $7 + 5$ equals 12, that only extended things can be green, that dynamite is explosive, and that one ought to act with due regard to consequences. I can state special reasons for considering each to be the case.

As to norms, I have the suspicion—backed up by psychological and

sociological theories—that corresponding special reasons are not so strong or so good as in certain cases of sensory experience, or of logic or mathematics. However, I have not found, and cannot formulate, any convincing general and direct criticism a priori of norms being true or false. Sometimes what norms *assert* is to me, and to many others, as compelling in their evidence and just as independent in their validity from my likes and dislikes as mathematical or any other propositions.

Is it an empirical question whether something is the case or not? My answer has been yes, but it seems to me now that the answer rests on an unduly general concept of ‘empirical’, taking it roughly to be equivalent to ‘ontological’. One may ask whether it is the case that an absolute proof of consistency is not available for the whole of arithmetic. I would say that the question is—as formulated—an ontological question, but not empirical. Maybe *factual question* is a better term; if something is the case or not the case, it is either a fact or not a fact. It is a factual question in contrast to one, for example, of terminological convenience or convention.

As to whether something *can* be the case, I agree with Österberg that this is a different question (from the point of view of connotation) from that of whether something *is* the case. Insofar as definitions of *true* and *norm* and related terms leave open the question of whether norms can be true, I do not see how it can be concluded that norms *cannot* be true. If definitions—or more general, conceptual structures—agreed upon by convention by very distinguished authors do not rule out a possibility, I cannot see that there remains anything else to do than to show that something *in fact* does not exist, meaning that there actually are not true (or false) norms.

Thus, I am not convinced that there is a logical flaw where Österberg sees one.

Österberg touches on a very important point in the following words:

It seems that value-objectivism can be intelligibly defended within idealistic philosophy. But what is the significance of this fact to a philosopher belonging to an analytical, empirical trend? Obviously he cannot adopt the conclusion that “norms can be true or false” if the premises are incompatible with the frame of reference within which he is thinking. Statements on this issue simply do not mean the same to a Simmel and a Carnap, even if they are given the same wording. So the whole argument of Professor Naess can be reduced

to the following: If our views on life were different, so would be our philosophical positions. If I had been Edmund Husserl, I would have been a phenomenologist. This is without a doubt true, but unfortunately with necessity.

(Österberg 1962)

I doubt very much that Österberg would find it adequate to say “Norms cannot be true or false because I think within a frame of reference such that norms cannot be true or false.” As soon as one can formulate a frame of reference, one does not think completely inside it, and one should be able to state whether it is considered to be expressing postulates, self-evident truths, and so on.

There are certain *fundamental* positions found among idealists or Platonists (Georg Simmel, Nicolai Hartmann, Edmund Husserl, Alonzo Church) such that, if they are believed in, one is likely to believe not only in the possibility but even in the actuality of true norms. Just because they are fundamental, it is hard to find a frame of reference that goes still deeper and from which the belief can be *shown* to be a false belief. At least I have not found an empirical or analytical position satisfying this condition. My conclusion is therefore that I do not *know* that (basic) norms cannot be true or false. Aristotle’s position seems to me wise when he denies that principles represent knowledge. What is so fundamental that it cannot be shown to be the case by reference to more fundamental (true) principles is not *known*.

If by a “fundamental frame of reference” or a “set of basic assumptions” is meant what I take it to mean, the ultimately ontological or factual question “What *can* be the case?” has no answer that constitutes a piece of knowledge. One may vehemently disagree that norms can be true or false, but this is no proof of the cognitive character of the disagreement.

In reply to Österberg, I would say that if one sees analytical and empirical frames of reference as special frames of reference at the same level as idealist and Platonist frames, one is apt to consider explications of the frames as sets of postulates rather than insights. In that case, answers to “What can there be?” and “What can be the case?” will be either postulates or derivations from postulates.

Österberg tries to show that by logical necessity norms cannot be true or false. According to him, “ought” has a primary use, and this use is such that it *necessarily* involves someone telling another to do something: it is

true that I ought to do *X* if an authority expects me to do *X*. Why, though, should one obey the authority?

In some instances of “ought,” Österberg’s analysis may be correct, but it is certainly not correct of those instances that are of interest in our present discussion. All authorities may be wrong: they may tell me that I ought to be an informer but I know I ought not. “Why should I obey?” is a pertinent question if I am told by somebody to do something. In judging “I ought to do *X*,” however, we do not encounter a question of obeying somebody else. There is a sense in saying “All authorities say I ought to do *X*, but nevertheless I ought to do *X*.” Whether this is a primary use I consider irrelevant in the present context; I think empirical investigations of the use of “ought” would reveal that “ought” is often used in this impersonal way, and I do not see how one could argue validly against that use in support of Österberg’s thesis.

Thus, hypotheses about the use of “ought” do not warrant our concluding that norms by logical necessity cannot be true or false.

As regards the theory of responsibility and choice suggested by Österberg, I am afraid I do not understand it. Whether I act according to a true norm or violate it, I am in both cases responsible for my action. Karl Jaspers, who seems to hold opinions similar to Österberg’s concerning the “I” and its “freedom,” does not see any incompatibility between objective validity of moral laws and the “inescapable” responsibility of the “I.” It adopts it and enables it to become itself. It seems to me strange that Österberg, from his point of view, can tell another person that norms by *logical necessity* (common to both persons) cannot be true or false. I do not pretend, however, to understand his theory. My remarks are therefore purely parenthetical.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he

has witnessed the most significant loss of cultural diversity and the onset of what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bioregionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cul-

SERIES EDITOR'S INTRODUCTION

tural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of “fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess's philosophical palette, not the "world" of his own consciousness as has become the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our

SERIES EDITOR'S INTRODUCTION

experience of the world is made up of gestalts. “[This] is the world we experience. Nothing is more real.”⁴ People create abstract structures to reflect on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess’s parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess’s “ontological realism” as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of “reality is one” plays a central role in the mature Naess’s approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality’s concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. “As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence.”⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess’s perspective, such accounts by themselves are merely a sign of cultural poverty. “God” could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess’s gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as “the social construction of

nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any "natural" tendencies toward anthropocentrism. As with Leopold's Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we "see" reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess's hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples' (or other life-forms') opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess's own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, "For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape."⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced

SERIES EDITOR'S INTRODUCTION

by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

SERIES EDITOR'S INTRODUCTION

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept

SERIES EDITOR'S INTRODUCTION

the premise “For every decision we, explicitly or implicitly, take all things into consideration,” then the notion of total views or total normative systems can be seen as very “useful fictions,” which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definite-

ness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. “We have all read it. We *still* cheat in argumentation, but now with feelings of guilt.”¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as “truth,” “democracy,” and “private enterprise.” . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

SERIES EDITOR'S INTRODUCTION

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly pro-

SERIES EDITOR'S INTRODUCTION

lific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of

SERIES EDITOR'S INTRODUCTION

land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a “great idea” without Doug’s generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of environment should not, in Naess’s view, play a pivotal role in shaping a budding philosopher’s development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess’s philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess’s principal writings. As such, the *Selected Works* is the definitive repository of Naess’s oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess’s philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded,
and should follow his questions wherever they lead.

Arne Naess, “Norway”

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the

SERIES EDITOR'S INTRODUCTION

unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He

SERIES EDITOR'S INTRODUCTION

loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for “collecting” and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family’s little “wilderness” before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother’s small mountain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours’ walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza’s *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess’s desire for a broad and open perspective, for seeing things in totalities (god’s-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth’s biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potentially influence his approach to philosophy.

Arne’s youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School’s first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others.

SERIES EDITOR'S INTRODUCTION

During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" —*sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical gram-

SERIES EDITOR'S INTRODUCTION

mar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of

knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather “witness” science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality (“maze epistemology”), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess’s interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess’s 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers’ intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related

SERIES EDITOR'S INTRODUCTION

these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as *"Truth" as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's "Common Sense and Truth" (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Ustaoset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created "institutes" of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into re-

SERIES EDITOR'S INTRODUCTION

search and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi’s catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi’s idea of trying to meet one’s opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war, Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO’s requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy*’s richness, diversity, and multiplicity of

SERIES EDITOR'S INTRODUCTION

meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess’s “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess’s empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess’s frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO’s plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess’s research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his

philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or im-

SERIES EDITOR'S INTRODUCTION

plied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last

group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation and Preciseness*, to argue that it is an illusion to assert that combined scientific and philosophical or "purely" philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN

SERIES EDITOR'S INTRODUCTION

IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V), was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), “Seek complete self-realization” and “Seek truth,” and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of “Self-realization!” as

the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical struc-

SERIES EDITOR'S INTRODUCTION

ture, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions taken earlier. Volume VIII includes sections on "Empirical Semantics and Truth," "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has

more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion, and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or

SERIES EDITOR'S INTRODUCTION

limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as “inventing” deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas’s 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson’s *Silent Spring*. Naess’s work on “deep ecology” can be subdivided into three main thematic areas.³⁰

What I refer to as Naess’s deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess’s general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work entering into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back

to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of "philosophical stupor," in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The "shallow," currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The "deep" approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach's proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans' special capacities for reason and moral consciousness come special responsibilities, particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the

SERIES EDITOR'S INTRODUCTION

Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-

evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only

SERIES EDITOR'S INTRODUCTION

who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy) make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally

than usual, rendering *praeclara* as “very clear” rather than the typical “excellent.”³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess’s distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this approach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people’s conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

SERIES EDITOR'S INTRODUCTION

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manuscripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and re-

SERIES EDITOR'S INTRODUCTION

ceive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface.

SERIES EDITOR'S INTRODUCTION

George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mul-

SERIES EDITOR'S INTRODUCTION

vaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible "work fairies" that were constantly pulling me back to my office don't actually exist. I can't wait.

Most of all, thanks to Arne Naess for placing his trust in me—it's been

SERIES EDITOR'S INTRODUCTION

a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora's box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne's writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder's "Axe Handles." The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five

SERIES EDITOR'S INTRODUCTION

hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Videos

Crossing the Stones: Arne Naess (Oslo: Norwegian Broadcasting Corporation, 1991), 47 minutes.

The Call of the Mountain: Arne Naess and the Deep Ecology Movement (Amsterdam: ReRun Produkties, Postbus 93021, 1090 BA, 1997), 50 minutes.

2. On Naess's effort to expand the concept of reason to incorporate emotions and feelings, see Arne Naess with Per Ingvar Haukeland, *Life's Philosophy: Reason and Feeling in a Deeper World*, translated by Roland Huntford, foreword by Bill McKibben, introduction by Harold Glasser (Athens and London: University of Georgia Press, 2002). As a testament to Naess's interest and influence in Norway, I note that in a country of about 4.5 million people, 150,000 copies of the Norwegian edition of *Life's Philosophy* have been sold. For a fine example of Naess's use of mythopoetics, see Arne Naess and Johann Brun (photographer), *Det Gode Lange Livs Far: Hallingskarvet sett fra Tvergastein* (The good, long life's father: Hallingskarvet from Tvergastein) (Oslo: N. W. Damm and Son, 1995). For other examples, see Naess's article on Tvergastein, his "Letter to the King of Nepal," and some of his writings on deep ecology in volume X of the *Selected Works*.
3. Most of these questions were drawn from Naess's discussion with Sir Alfred Ayer on the nature of philosophy and the problems it seeks to address (Naess and Ayer, "The glass is on the table," p. 14).
4. See Naess's "Ecosophy and gestalt ontology" in SWAN X.
5. Jakob von Uexküll, "A stroll through the world of animals and men: A picture book of invisible worlds," in *Instinctive Behavior*, edited by Claire H. Schiller (New York: International Universities Press, 1957), p. 14.
6. Arne Naess, "Validity of norms—But which norms? Self-realization? Reply to Harald Ofstad," in *In Sceptical Wonder*, p. 259.
7. Naess and Ayer, "The glass is on the table," p. 59.

SERIES EDITOR'S INTRODUCTION

8. For more information on Naess's theory of normative systems, see "Notes on the methodology of normative systems" in volume X of the *Selected Works*. For details on his application of normative systems, see *Communication and Argument* (SWAN VII) and *Gandhi and Group Conflict* (SWAN V) as well as Naess's discussion of Ecosophy T and "Philosophy of wolf policies I" in SWAN X. For an entire book dedicated to exploring the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," see Naess's *Gandhi and the Nuclear Age*, translated by Alastair Hannay (Totowa, NJ: Bedminster Press, 1965).
9. See Naess's "What do we as supporters of the deep ecology movement stand for and believe in?" in volume X of the *Selected Works*.
10. Letter to Doug Tompkins, May 26, 1992.
11. Justus Hartnack, "Scandinavian philosophy," in *The Encyclopedia of Philosophy*, edited by Paul Edwards, vol. 7 (New York: Macmillan, 1967), p. 301.
12. From about 1845 to 1910, Hegelianism dominated Norwegian philosophy. This period is often referred to as the "dead period" of Norwegian philosophy, not because of Hegelianism but because it was characterized by a dearth in publishing.
13. Personal communication, April 30, 1997.
14. Alastair Hannay, "Norwegian philosophy," in *The Oxford Companion to Philosophy*, edited by Ted Honderich (Oxford: Oxford University Press, 1995), pp. 626–27.
15. Gullvåg and Wetlesen, *In Sceptical Wonder*; Alan Drengson, ed., *The Long-Range Deep Ecology Movement and Arne Naess*, special edition of *The Trumpeter* 9 (Spring 1992); Rana P. B. Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher

SERIES EDITOR'S INTRODUCTION

Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.
21. See Arne Naess, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior or, more colloquially, Science as behavior), Inaugural Dissertation (Oslo: Norwegian Academy of Sciences, 1936).
22. John Dewey, "Experience, knowledge, and value: A rejoinder," in *The Philosophy of John Dewey*, edited by P. A. Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.

SERIES EDITOR'S INTRODUCTION

24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.
25. Arne Naess, "Reconnaissance, 1949," in *Tirich Mir*, p. 22.
26. See *Life's Philosophy* (note 2); Arne Naess, *Gandhi* (Oslo: Universitetsforlaget, 2000); Arne Naess, *Det Frie Menneske: En Innføring I Spinozas Filosofi* (The free human being: An introduction to Spinoza's philosophy) (Oslo: Kagge Forlag, 1999); and Øyvind Grøn and Arne Naess, *Introduction to General Relativity and Its Mathematics* (Oslo: Høgskolen i Oslo, 1998).
27. See Gullvåg and Wetlesen's *In Sceptical Wonder* for Galtung's "Gandhian themes" essay on what he calls Gandhian topics and Naess's way of dealing with them in *Gandhi and Group Conflict*. Naess's other books on Gandhi are *Gandhi's Politiske Etikk* (Gandhi's political ethics), coauthored with Johan Galtung (Oslo: Johan Grundt Tanum, 1955); *Gandhi and the Nuclear Age*, translated by Alastair Hannay (Totowa, NJ: Bedminster Press, 1965); and *Gandhi* (Oslo: Universitetsforlaget, 2000).
28. Arne Naess, *Equivalent Terms and Notions in Spinoza's Ethics* (Oslo: Filosofisk Institutt, Universitet i Oslo, 1974).
29. For a discussion of nonanthropocentrism as part of an ongoing historical tradition with ancient roots, see George Sessions, "Ecocentrism and the anthropocentric detour," in *Deep Ecology for the Twenty-First Century*, edited by George Sessions (Boston: Shambhala, 1995), pp. 156–83. For details on Douglas's effort to save the Everglades, see Marjory Stoneman Douglas, *The Everglades: River of Grass*, rev. ed. (Sarasota, FL: Pineapple Press, 1987).
30. See Arne Naess, "The shallow and the deep, long-range ecology movement: A summary," *Inquiry* 16 (1973): 95–100 (in SWAN X). For a more detailed, mature version of deep ecology, see Naess, "The deep ecology movement: Some philosophical aspects," *Philosophical Inquiry* 8 (1986): 10–31 (in SWAN X). For a concise overview of deep ecology that chronicles its key evolutionary changes and identifies the distinctions among the "deep ecology approach to ecophilosophy," the "deep ecology movement," and Naess's

SERIES EDITOR'S INTRODUCTION

"Ecosophy T" (a particular deep ecological total view), see Harold Glasser, "Deep ecology," in *International Encyclopedia of Social and Behavioral Sciences*, edited by Neil J. Smelser and Paul B. Bates (Oxford: Pergamon, 2001), pp. 4041–45. For a detailed discussion of deep ecology as an ecophilosophical approach with special attention to its policy implications and a discussion of deep ecology's relationship to Naess's earlier philosophical work, see Harold Glasser, "Naess's deep ecology approach and environmental policy," *Inquiry* 39 (1996): 157–87 (reprinted in Witoszek and Brennan's *Philosophical Dialogues*).

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was

AUTHOR'S INTRODUCTION TO THE SERIES

"A philosopher." In fact, I had already conceived of myself as one. I viewed the writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that "What do I mean?" is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these "ordinary" people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems

AUTHOR'S INTRODUCTION TO THE SERIES

discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my

AUTHOR'S INTRODUCTION TO THE SERIES

knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclination very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

AUTHOR'S INTRODUCTION TO THE SERIES

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions for improving the readability of the first editions of *Scepticism* (SWAN II),

AUTHOR'S INTRODUCTION TO THE SERIES

The Pluralist and Possibilist Aspect of the Scientific Enterprise (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity, attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Preface

by Alan Drengson

The breadth of subject matter in these eighteen essays by Arne Naess is apparent from the first four section titles: (1) Democracy, Ideology, and Rationality, (2) Philosophy of Science, (3) The Philosophy of Peace and Gandhian Ethics and Communication, and (4) Spinoza. Then, in the final two essays in this volume, Naess explicitly relates the scholarly pursuits of his professional life to larger practical issues about which he cares deeply. The first piece in section 5 (originally published in 1983) gives us an overview of Naess's philosophical development throughout his career as a scholar, educator, and social activist, beginning with his first reading of Spinoza while still in high school. In the second piece ("Deep Ecology and Education," first published in 2000), he describes how he became a leading spokesman for the international deep ecology movement.

The close connection between Naess's scholarly work and his wide-ranging social and environmental concerns can be discerned throughout this volume. In section III, for example, Naess discusses the relevance of his work on Gandhi and nonviolent resistance to the peace, social justice, and ecology movements. (SWAN V, *Gandhi and Group Conflict*, is devoted entirely to Gandhi's philosophy of nonviolent activism.) Over his long life as an active scholar, philosopher, and mountaineer, Naess has applied his scholarly knowledge and research skills to furthering the main principles of the grassroots movements that aim for social justice, an end to war, and the nonviolent resolution of disputes. A nonviolent stance in our relations with the natural world is supported by the movement for deep ecological responsibility. For all these movements, nonviolence in language use is of uppermost importance for positive communication. Naess has always been strongly motivated to work for positive understanding and better commu-

nication. He is not a pure theoretician but rather tries to solve practical problems in relationships through Gandhian communication and improved clarity. Both in his methods of teaching and in his philosophy of education his aim has been to empower people confidently to develop and articulate a personal philosophy of life based on their ultimate values and view of the world (see chapter 18). This, he believes, is part of being a well-integrated person with a sense for the world as a whole. In logic and argumentation courses, he aimed to empower students to reason well, to state their views clearly, and to help others clarify their own views. These methods and aims make congenial learning and research possible.

Much of Naess's energy has gone into promoting greater clarity and better understanding through improved communication and education. Issues of communication and interpretation came together in his first major work (SWAN I). Helping him to advance this work were the lessons Naess learned in the 1930s from participating in the discussions of the Vienna Circle (chapter 17). Circle members showed him that philosophical and research undertakings are not necessarily adversarial but can be based on mutual respect and cooperation. In much the way that researchers work cooperatively to unearth fossils (Naess worked on a dig in North America), philosophers can work together to understand better the exact nature of human disputes and conflicts resulting from failures in understanding that, in turn, result from failures in communication. Interpretation is always involved when we use language, written or spoken, and the various interpretations necessarily exhibit personal features, colored as they are by cultural differences and unique personal experiences.

From his earliest days as a professional researcher, Naess has held in high regard the abilities of ordinary people (chapters 17 and 18). In his studies of *truth* as defined by experts and by ordinary people, he found that the nonexperts managed to come up with all the views articulated by the experts—and some others as well. In talks with Noam Chomsky and other theoreticians of language and philosophy of language, Naess found that their interests were primarily focused on syntactics, generative grammar, and theories about language that were not directly applicable to reducing conflicts and avoiding misunderstanding. They were working out details of abstract theoretical knowledge. In contrast, he favors looking in depth at what people actually say and do with respect to important central concepts

such as *freedom* and *democracy*. In that way, we can improve understanding in a wider context.

Naess has sometimes described himself as a wandering seeker (zetetic) of truth, knowledge, and wisdom (see, for example, SWAN II and VIII). His approach to philosophy is Spinozan in that he looks for the applied, daily-life implications of his philosophy of life and his global vision. Reading Spinoza for the first time when he was seventeen, Naess was inspired to try to articulate his own worldview and philosophy of life. He appreciated the way Spinoza articulates his grand vision by means of geometric exposition aimed at leading the reader to the same unitive insights and intuitions that Spinoza himself had about the integrity of our whole experience (see, especially, chapters 12, 15, and 16, “Is Freedom Consistent with Spinoza’s Determinism?,” “Spinoza’s Finite God,” and “Einstein, Spinoza, and God”).

Spinoza’s discussions of emotions and freedom are central in Naess’s interpretation of the *Ethics*. Unlike most Spinoza scholars, Naess thinks these qualities not only lie at the core of Spinoza’s philosophy of life but are of great practical importance in the modern age. Spinoza teaches a way of life that is joyful. His teachings on feelings are close in spirit to some of the great philosophies of life from the East, such as the form of Buddhism that Naess discusses in this volume (chapter 13, “Through Spinoza to Mahāyāna Buddhism, or Through Mahāyāna Buddhism to Spinoza?”). Spinoza’s emphasis on active, positive emotions as a way to freedom also sheds light on the life-denying features of negative, passive feelings. For Naess, Spinoza is a philosopher who sees life whole and, moreover, is able to sketch his total view through carefully defined terms and axioms expressed in Medieval Latin (chapter 14, “An Application of Empirical Argumentation Analysis to Spinoza’s *Ethics*”). Naess’s appreciation for the complexities and depth of Spinoza’s texts leads him to the recognition that there cannot be a single definitive interpretation of those texts. Like so many philosophical (and other) texts, they are rich and deep in possibilities that even the author himself did not fully recognize. As Naess points out, texts do not usually have a guide that explains how they are to be read and interpreted—and even if they had such a guide, the guide would have to be interpreted.

A reading of all the papers in this volume allows one to pick up the main themes that run through Naess’s ways of writing, researching, and thinking. He regards our spontaneous, uninterpreted experiences of the

world as far richer than we can ever express in any language (chapters 17 and 18). When we learn our native languages, and then specialized ways of symbolizing our thoughts and feelings, we are able to produce texts that become artifacts with a narrative life of their own. They become part of a body of literature with criticism and commentaries. This is true on many levels and for many types of documents used in a variety of settings, from constitutions and treaties to manifestos and political propaganda. Even when people come from the same culture and speak the same language, there can be widespread disagreement about how to read such documents, just as there are with religious and philosophical writings. Within a single tradition differences exist, for example, between spoken language, literary or poetic writings, and scientific textbooks. Often, too, there are contexts and specialties devoted to interpretation of key documents: court decisions, legislation, and the like. When cultures having different languages and histories, plus different religions and worldviews, encounter each other, these interpretive differences can increase exponentially. Under such circumstances, difficulties in understanding can easily develop. People sometimes feel threatened by worldviews they see as competing with their own values, and they cannot make sense of what their perceived opponents are saying. The result can be open conflict, escalating violence, or even widespread war (see, for example, chapters 1–3, “The Function of Ideological Convictions,” “Analytical Survey of Agreements and Disagreements,” and “Ideology and Rationality.”).

During the Cold War enormous tension developed between the Eastern Soviet Bloc and the West. Politicians in the West asserted that the Soviet system was not a democracy as there was no freedom of press, expression, or religion within its sphere of control. Some key Soviet documents, however, seemed to favor freedom and democracy. Naess compared how certain key terms were used by Russian writers (see his discussion of Zaslavski’s texts in SWAN I) and how the same terms were used by authors in the West. Later, he took part in an ambitious study funded by UNESCO to find out exactly what different people—experts, policymakers, and others—thought about key concepts such as *freedom* and *democracy* (chapter 2). Eastern and Western experts and policymakers were polled by means of questionnaires and documents on which they were asked to comment.

Naess’s UNESCO research showed that no clear consensus about these

matters existed in either camp. Neither side, it turned out, exhibited very much internal agreement. This research was undertaken using a methodology that Naess had helped pioneer in earlier studies of scientists doing science and of what experts and nonexperts think about *truth* (SWAN VIII) and intrinsic values in Nature (SWAN X, chapter 18). The methods developed and used were part of his engagement in empirical semantics (see also SWAN I, VII, and VIII), a descriptive discipline that attempts to understand how language functions in everyday life, in various academic and other specialties, and cross-culturally. While other philosophers were assuming they knew what ordinary people meant by various words, Naess decided that we should observe and ask questions. When others speculated on how science is actually done, in their attempts to clarify what science is, Naess conducted empirical research by observing experimental psychologists working with rats. (Naess himself had also done experimental research with rats; see chapter 17.)

In using Naess's approach, one soon learns that the actual practice of science is considerably more diverse than would appear from reading textbooks about science. In texts about science, we are given to understand that there is consensus, that all scientists more or less think and do the same things. Naess shows that the idea of a specific scientific worldview, complete with all the *it*'s crossed and *is*'s dotted, does not follow either from historical studies or from observations of the current state of science in the West. Moreover, the historical studies of science in the differing traditions of East and West lead us to identify an even greater diversity of views regarding how the world is to be understood and related to, and how human beings should value and work with it.

Science as open inquiry is based on the integrity of individual researchers (chapter 5, "A Plea for Pluralism in Philosophy and Physics"). One could say that in this sense it is a democratic undertaking, since people and communities should be free to make their own observations of how things happen in their own places. In modern industrialized societies, however, science has become a professionalized enterprise, a place or cult for the expert and specialist (chapter 6, "The Case Against Science"). In addition, special interest groups and government policies strongly direct scientific undertakings in the industrialized world, funding or not funding research according to their own priorities. As we know from much experience, sci-

ence as an enterprise has not always worked to further freedom, nonviolence, and democracy (for more on this, see SWAN IV).

The modern approach to science, pursued after 1550 in the West, is unique in the emphasis it places on prediction and control and in its development of highly specialized disciplines that fragment our knowledge of the world. The world, Naess has always felt, is one. Reality is one, but it is multifaceted and there are endless ways to describe it. One of the important lessons learned from the study of global ecosystems is that human cultures are interacting parts of these systems and, as such, should not be thought of as outside them (chapters 17 and 18).

Beginning early in his life, Naess's approach to open inquiry has combined all his interests with a desire to articulate his total view using all forms of knowing and experiencing, all types of methods and experiments, always guided by a philosophy of nonviolence and respect for individuals. He has distilled the values at the core of his personal philosophy into a single fundamental norm, "Self-realization!" which he then expanded to "Self-realization for all beings!" (chapter 17). He became aware early in life that we have a sense for the wholeness and unity of the world that comes from our undivided spontaneous experience of it as we are fully in it, such as while wading in the sea or walking in a mountain meadow. For all of his adult life Naess has been an alpine mountaineer, a follower of Gandhi, and a wandering seeker who decided early on that it was his life's calling to be a philosopher in Spinoza's way.

Throughout the essays in this book, we see evidence of Naess's wide-ranging interests as well as his commitment to open inquiry and nonviolence. He strives to be inclusive and generous. In all his undertakings he tries to bring about better communication and understanding by using a variety of methods. He feels that it is a sign of maturity when we appreciate diversity on *every* level, from personal to cultural. As Spinoza said, the more we know about the world, the greater our appreciation for the way things are, and then we realize that our smallness is a way of being in tune with God, or the ultimate. Our freedom is found through deeper understanding and through emphasizing positive active feelings (chapter 12, "Is Freedom Consistent with Spinoza's Determinism?"). Deep understanding depends on nonviolence, even in attitude. When we sit quietly in a meadow or a tidal pool, the lives around us return to normal.

Another realization that came to Naess early in life was that he did not want to become a specialist. He wanted to understand how the world hangs together and what the most important values are for having a meaningful and joyful life. He found his joy in mountain climbing and in the search for interdisciplinary knowledge, communication, and understanding. These have distinguished his career. Through his empirical and logical studies he came to appreciate that there are no value-free inquiries. All knowledge pursuits are value-laden; even pure logic assumes certain values, such as consistency. Comprehensive knowledge leads to understanding, and each of us acts *as if* we had a total view, even if we cannot articulate it very well. The better we understand and can articulate our own total view, the more confidence we have and the better we can communicate with others about our thoughts, feelings, and values.

Naess has devoted considerable effort to clarifying and exploring normative systems and qualitative evaluations of experience and the world. In his youth he loved math, logic, and other quantitative subjects. As he grew older he realized that the Earth's material resources are limited and that we must put a cap on material consumption. In the domain of quality of life and deep experience, however, there are great possibilities for endless expansion. For example, there are countless ways to appreciate beauty in the world. Even if we only improved the quality of our immediate relationships at home, our life quality could rise enormously. There are so many ways to find joy in the smallest things in the world around us that science can be a wonderful undertaking at any age. Science and philosophy should not, in Naess's view, be the special province of adult experts; they should be open to everyone. We can develop and use all sorts of ways to learn more about the world and life, about values and quality of experience, provided we exercise our creative imaginations, are willing to apply ourselves, and are willing to act freely with an open mind. As a wandering seeker Naess searches for knowledge and truth. He states his ultimate values and assumptions about the world, but he never claims to have the one defining right view. He encourages others to state theirs and he finds joy in this diversity.

Even when the great pluralism of worldviews, cultures, and ways of doing science seem inconsistent with one another, conflict can be avoided. (These issues are raised in chapters 5, 7, and 8, "A Plea for Pluralism in Phi-

losophy and Physics,” “On the Structure and Function of Paradigms in Science,” and “Why Not Science for Anarchists Too?”) Just as we learn to live with inconsistencies in our personal lives, so we can come to appreciate the cultural, religious, and philosophical diversity on Earth as akin to the biological, ecological, and individual diversity found throughout the natural world. Naess shows by his example that appreciating this diversity can lead to a sense of unity on a global scale, since with maturity and wisdom we realize that diversity is life’s way of creating energy. Acting in generous and beautiful ways by giving more to the Earth than we take (chapter 18), more to our community than we take, and more to future generations, we can help to build a world without war, with ecological sustainability and social justice, and yet with diverse cultures. (On the end to violent conflicts, see chapters 9 and 11, “Nonmilitary Defense” and “Consequences of an Absolute *No* to Nuclear War.”)

One key to peace is a better understanding of the nature of languages as they are actually used. How do they shape the lives, feelings, and thoughts of people in different cultures around the world? This study, as exemplified by Naess, leads us away from dogmatism, from thinking our way is the only way. We realize that there are many wonderful possibilities for creating ever greater diversity with sustainable cultures of place. Unfortunately, there are forces working against this deep movement under the guise of a globalization that aims to control other nations as a first step toward turning them into modern Western consumer societies. Naess has worked to realize other possibilities, among them the combination of localization with international cooperation for global concerns (chapters 17 and 18). He welcomes thriving vernacular cultures that preserve the integrity of the natural world in their home places. He also stresses the importance of international cooperation with commitment to principles cutting across cultural boundaries, such as the platform principles of the deep ecology movement. He has shown a way for reason, democracy, and science to flourish in freedom and diversity.

Author's Preface

Reflections on My Papers and the Selections in SWAN VIII–X

During my active life as a researcher and author, I have published far too much to be a polished writer. I have a long practice of working a set number of hours each day, and at ninety-two I have lived a long life. I hold to this even when I live in my mountain hut, Tvergastein. Over the years I have carried in many precious big reference books to put in its “library.” Writing philosophy in the hut, while looking over a vast mountain and alpine landscape, gave me a different feeling and perspective than when working in my office at the university or in my study at home. Each setting is very different and seems to bring out different aspects of the same subject and of myself. There are also the differences in dialect and local customs that fed my search for an ever more complete total view. To me this diversity is good to appreciate for its own sake. Writing, like teaching, is a way to find out things rather than just a dull report on the past. Writing philosophy for me is an ongoing project, a kind of meditation; in a sense, it is something that I must continue daily, because I continue to have more and more gestalts integrated into my total view with feelings of wholeness.

I never regarded the papers or even the books I wrote to be final drafts, but always works in progress, since my life, philosophy, and worldview are all in an ongoing process of change. Altogether, I have probably written thirty or so books published in various languages, and some in several languages. I have had many coauthoring adventures. There are manuscripts of books started but still in progress. I probably have some finished but unpublished book manuscripts. In the area of smaller-scale publications and writings, there are many kinds of pieces from very short to very long—for example, short reviews, long reviews, discussions, definitional pieces, long

AUTHOR'S PREFACE

single-subject essays, historically oriented papers, formal logic pieces, empirical studies, studies of conceptual systems—pieces on so many different subjects that I am somewhat embarrassed by my lack of attention to other things. I almost always write with passion but am not so keen to keep detailed records of my scholarly research, and at Tvergastein these resources are limited.

I have hundreds of manuscripts of articles, reviews, and other nonfiction pieces in my collection. The SWAN project has been a wonderful undertaking because it helped me to get my works organized to be more accessible to a larger audience. My dear wife, Kit-Fai, has been so good to my work that I can only describe her acts as beautiful. She, along with Harold Glasser, Alan Drengson, and others, plied me with endless questions about my works and individual pieces, for references, for greater clarity, for a better organization in time, and so on. The result is an assemblage of more than seven hundred published and unpublished papers.

We were choosing books to publish and papers for the anthologies of my selected works in English. We settled on seven books to be republished as the first seven volumes in the SWAN series. After some discussion with others, we decided to have three volumes of my papers for a total of ten volumes. We pondered what to include in the anthologies of papers and how to organize them. The result is a collection of writings that is a very deep and broad representation of the large number of papers of my work. The first two volumes are devoted to all the subjects I have worked on, from earliest to latest. These collections (SWAN VIII and IX) are organized in thematic sections somewhat chronologically. We decided to devote the third collection to my writings on deep ecology, because they are the most complete example of a total view that I have been able to offer.

Deep Ecology of Wisdom (SWAN X) is in many respects the most complete volume in the series in that it shows the total sweep of my work. It shows how my comparative and ecological inquiries brought together all my interests and studies. It was also a natural place for me to apply empirical semantics guided by a personal mythology, an undertaking that in the 1990s was offered in my book *Hallingskarvet: How to Have a Long Life with an Old Father*. The Tvergastein article in SWAN X (chapter 33) is an example of the philosophical, empirical, and semantic studies that were saturated with this place through time. SWAN X also includes a comprehensive bib-

AUTHOR'S PREFACE

liography of my works in English, which gives readers the most direct access to this whole body of work. Everything in my work is represented, from Spinoza's philosophy on emotions and Gandhian nonviolent communication, to essays on ontology and mountaineering. All of my work comes together in SWAN X. Readers will see the role of my desire to further nonviolent communication and my scepticism about there being only one worldview that is "true." These reflect my love of diversity.

I have mountain perspectives on worldviews. So many of them are beautiful and so suitable to their places! It is a wonder for me to behold this creative diversity. I found the same on the ground around my hut in the extreme mountain arctic conditions there. Even there, worlds within worlds! In that setting, life energies and mysteries are ever present. I came to approach all research from philosophy to ecology as if I were a field naturalist. This is reflected in my writings. Writing for me is a process of creation, discovery, and systematization; an art that helps me to assimilate and be whole with the more I see, as time goes on, from so many different perspectives. A synoptic view, almost holographic, emerged in my writings in many places. Traveling a lot added to learning these things.

Questions of meaning, preciseness, and interpretation are central to all that I do. We greatly underestimate ourselves in relation to our capacities, but we also greatly overestimate (violently at times) the seeming importance of disagreements over words that are frankly not very precise. The very effort to become more precise is itself an enlightening process that, once started, continues with a natural flow on its own. It is a settled practice that flows through my writing. Gandhian nonviolent communication also runs through my daily writings and practices; it is a second nature. My writings are active engagements, and for this reason I do not find them boring or painful. It is a joy to write about these many subjects that have engaged my passionate interest, especially in relation to the natural world.

Readers of these three volumes of selected papers who want to see my work in a more or less organic way that is roughly historical should read these papers in order, SWAN VIII through X. Those who want an overall look at my whole program of research, writing, and lifestyle should first read volume X. They could also read the last two chapters in SWAN IX, "How My Philosophy Seemed to Develop" and "Deep Ecology and Education: A Conversation with Arne Naess."

AUTHOR'S PREFACE

I have been reflecting on my writings and the way I approach and feel about this work. Let me say something about the different research hares I have chased and the lesser peaks and major mountains I have climbed in the process. I will do this by focusing on a recent ten-year period, from 1987 to 1997.

What has made me eager over the decades to continue writing articles in such great numbers? My spontaneous answer is that these are important questions not only for me but also for everything that it is worthwhile to sustain or develop further. By chance, this very sentence exemplifies a question of this kind: what is meant by “not only for me but . . .” and who is the “me” here? Among such questions there are some to which, as an optimist, I feel I can still contribute. These questions fall into two categories: those related to the ecological crisis and those philosophical questions far away from the ecological crisis. Writing for me is a series of adventures that are part of a larger mythopoetic nature narrative.

I thought that in recent decades the environmental crisis articles would make up the majority of my papers during this time, but to my astonishment that is not the case. For example, in the five years from 1991 to 1995, 61 percent of the articles published [by 1997] deal with general philosophical issues, and 68 percent of the unpublished ones are of that kind. Some of the articles are short, only five pages, which in part explains the large number of articles—78 published and 130 unpublished—during this time. I do very little to get my articles published.

One of the philosophical articles has the title “We need philosophies as life- and worldviews.” Many articles, some used in lectures in various parts of the world, deal with what I hope will characterize university philosophy in the twenty-first century: addressing central questions of what constitutes a meaningful life, diversity of cultures, and the nature of reality. Who are we, where are we, and what do we want most? The last question concerns value priorities. University philosophy, *not* the philosophy of “the man in the street” or of writers in general, has been centered on our talk itself, not on what we talk about. It is often talk about talk. The latest fad has been to stop talking about the variety of conceptions of the world in favor of talking about what are called social constructions, just to mention a focus different from life philosophy and worldviews. (Is nature a big *social* construction?) Clearly, as soon as we start *talking* about anything, for example,

about what is “talk,” what is “social,” and what is a “construction,” we are using a *social* creation, *intersubjective* talking. This does not undermine our excellent, direct relations to the matters we talk about and, I am glad to say, have different views about, some of which are quite personal and individual.

I will not bother to explain all the approaches I have taken within the philosophical sphere. I shall only offer some hints. In ethics I have taught, lectured, and written on the conception of being a “traitor,” a word applied to tens of thousands of Norwegians who in different ways were “on the wrong side” during the Nazi occupation of Norway by Germany. Many who did not deserve it were put in prison. Many believed that Hitler would win the war and that the continued independence and freedom of Norway depended on maintaining good relations with the occupying power.

Norway twice has said “No thank you!” to joining the Common Market, now called the European Union. I have written against joining on the basis of a philosophy that favors cultural differences. The EU is a big step in the direction of economic globalization, a formidable obstacle to cultural integrity and diversity. Some call this effort of mine “applied philosophy,” and I agree.

I have called a class of life- and worldviews *Spinozistic*, and my own view belongs to this class, but that does not *imply* accepting as true or valid any of Spinoza’s axioms and theorems. A long series of my articles deal with Spinoza, especially the central position of strong active emotions as a requirement for increasing our freedom and power, a rather un-Western view! I have explored and written about many Eastern philosophies, including Indian and Chinese. Some of my articles compare Spinoza’s views with Buddhist philosophies.

Gandhian studies continue with what I call the “principles of Gandhian communication,” a form of strict nonviolence. The role of the mass media in tough conflicts makes fairness of central importance. Treatment of an opponent as a fellow human being must be without blemish, even when his views seem to be, or are, horrible, despicable, and idiotic—and even if he is a mass murderer. This treatment is *compatible* with the expression of a strong and honest rejection of the views and actions of an opponent.

Felt suffering has been an important theme in my papers for many years. There is a strange, socially and politically important underestimation of acutely felt suffering and an overestimation of a quantified but not necessar-

AUTHOR'S PREFACE

ily *felt* suffering. If by chance a hundred people living distant from one another simultaneously suffer from a slight headache, this multiplicity of persons does not make the felt suffering stronger. I am deeply interested in the quality, the *feelings* of strong suffering, not some “abstract sum” of suffering.

Suppose we have a chance either to rescue a person from continued, systematic torture or to diminish the slight pain of a million people. As I see it, the choice is ethically unproblematic: rescue the tortured person! Politically, the implication is clear: much greater effort is needed to help people in certain extreme conditions. This, of course, cannot be done without angering dictators. What I call the *intensity principle* in dealing with suffering is generally not considered valid, and the possibility of saving people from continued torture is judged to be very small. As I see it, the problem is that usually only conventional means are considered. We need people with imagination, people like those who rescued thousands of tortured persons during the Second World War and the occupation.

As a philosopher influenced by analytic philosophy and an admirer of mathematical physics, cosmology, and pure mathematics, I regarded the one-hundredth jubilee (1991) of the birth of Rudolf Carnap and Hans Reichenbach as an opportunity to rethink my opposition to their philosophical standpoints and to logical positivism in general. I deeply respect their work, and especially their clearness in the matter of premise-conclusion relations. I have worked hard with a normative system that has only one ultimate normative premise, “Self-realization!” It is a result of the influence of my studies in logic and formal systems. In their work, the logical positivists encouraged each other, discussed with fairness, and used each other’s insights. They were not afraid of real disagreements. This is very unusual in intense philosophical discussions! I try to be fair and cooperate in discussions with my critics in social ecology and ecofeminism.

Going back to the five years from 1986 to 1990, I see that my papers are colored by contributions to the deep ecology movement. There is, however, a notable exception in my writings: what I call *gestalt ontology*. Ontology is an old branch of philosophy that tries to characterize what is real compared to what only appears to be real. Might a birch be bright green and joyful, or is it *really* colorless? Is joyfulness perhaps only a “projection” of joy being felt by an observer? Very roughly, my answer is that *spontaneous experiences* are direct experiences of something real. Joyfulness is

AUTHOR'S PREFACE

on a par with tallness and specific weight, when we only talk about pure realness. The experiences have a gestalt character. They are complex wholes, not merely atomistic.

The focus on spontaneous experience may be of positive value for deepening and intensifying positive experiences in nature. This focus also accepts the status of negative experiences. If, for example, a city dweller exclaims "Horrible, threatening" when suddenly facing a large waterfall, it is inappropriate to counter with the assertion "You are mistaken. It is really beautiful!" As to the character of being threatening, one might say that it would be a mistake to predict that the water will engulf us. This is just what gestalt ontology says. We can even have a slightly different version; it leads into rather professional philosophical terminologies. Its main thrust radically undermines the claim that only the exact physical sciences show us what is real. On the contrary, they increasingly focus on extremely *abstract structures* of what is real and do not, as sciences, describe any *concrete contents*.

As an outline of my work (from 1987 to 1997), the above gives a rough picture that is a fair description for earlier periods. I should perhaps add a word about my only published book in the 1990s: *Hallingskarvet: How to Have a Long Life with an Old Father* (1995). The main title is the name of a great Norwegian mountain; the subtitle refers to my personal relationship with the mountain. Already at age ten, I looked upon this mountain as being like a wise, benevolent father, but also as a supreme place to live. (My own father died when I was about a year old.) I found in this place an outline of my *mythopoetic life vision*. Many others, I suspect, are today creating such valuable myths of their own. I hope my writings encourage them. If so, these works will serve a useful purpose. So, finally, I am at the end of this written narrative. I invite readers to find their personal paths through this varied and multidimensional terrain of my writings. Follow your own wild passionate feelings.

Analytical Survey of Agreements and Disagreements

Introduction

In its recommendations for the use of material collected through the UNESCO inquiry into ideological conflicts, the Committee of Experts, which met in May 1949, suggested that an analytical survey of agreements and disagreements explicit or implicit in the material be worked out and published along with a selection of significant contributions received in response to the inquiry. On the following pages an attempt will be made to trace the outlines of such an analysis.

To facilitate assessment of the validity of whatever conclusions are suggested in the following, a few remarks on the character and limitations of the material under scrutiny are called for.

The inquiry undertaken by UNESCO was from the outset conceived as an enterprise in philosophical analysis: in analysis of meanings, conceptual differentiations, theoretical implications, and normative foundations. The preparation of the inquiry was guided by the idea that considerable progress toward the clarification of the grounds of current conflicts could be made through the initiation and organization of philosophically detached debates across national and ideological frontiers. Several avenues of approach to the implementation of this idea were discussed. The assembling of general essays on themes like “the nature of ideological conflicts,” “disagreements over democracy,” “the essence of democracy,” and so on, was found to be of little avail. Some device had to be found that would en-

DEMOCRACY, IDEOLOGY, AND RATIONALITY

sure a higher degree of comparability between opinions held on the more precise problems involved in the general issue. In an effort to achieve this end, a fairly detailed questionnaire was worked out. In its final form,¹ this questionnaire did not make any pretensions toward exactness in its formulations but was mainly intended to induce scholars and experts to focus their discussions on approximately the same range of basic problems and thus make it possible to reach a clearer picture of the location of agreements and disagreements.

The questionnaire thus devised was distributed directly or through National Commissions to almost six hundred philosophers, political scientists, jurists, historians, sociologists, economists, and others who had given evidence of interest in the foundations of ideological conflicts. Of those thus approached, more than one hundred sent in direct contributions to the inquiry. Others confined themselves to referring to or sending books or articles in which they thought they had already stated their views on the problems at issue. Still others explained that lack of time and the urgency of other commitments prevented their taking part in the inquiry. A few of those approached complained of the abstruseness, or futility, or both, of the undertaking, but on the whole the reactions registered were positive and sympathetic.

A considerable number of these contributions took the form of letters discussing one or more aspects of the problems at issue. Others were confined to laconic replies to the questions listed or consisted of short notes on a small number of points that had been found particularly important. A majority of the contributions, however, were fairly thoroughgoing in analysis and argumentation and were undoubtedly based on conscientious rethinking of the problems in terms of the approach adopted by UNESCO. Some of these took the form of general essays on the theme of the inquiry, and a few actually comprised monographs on more limited topics like the history of the usage of "democracy," the Marxian conception of "democracy," Soviet definitions of "democracy," and so on. Most of the more thoroughgoing contributions, however, kept fairly close to the order of questions in the questionnaire: although very few respondents found it worthwhile to work out replies to *all* the questions, a great many gave their views on more than half the questions.

A small number of the contributions were mimeographed and distributed to other contributors for cross-discussion of points of disagreement.

Unfortunately, only a small beginning could be made within the framework of the UNESCO inquiry toward systematic organization of such cross-discussion. A few samples of comments and replies to comments were included in the UNESCO volume described in the introductory note to the first article in this section and in the notes to this article.

The material made available through the UNESCO inquiry cannot in any way claim to be representative of world opinion in a statistical sense. Nevertheless, the material may be said to make up a significant cross section of enlightened opinion on the foundations of current conflicts concerning democracy. All the major trends of ideological thinking in the world of the postwar era have, in one way or another, found expression in the material, but unfortunately not always in direct proportion to their world importance, however that may be measured.

In the account of agreements and disagreements that follows, no attempt has been made at statistical tabulation of the data in the material. Given the relatively small sample and the geographical as well as ideological arbitrariness of the distribution of responses, any effort toward quantification would seem futile. Instead, all cases of complete agreement or disagreement have been explicitly noted; intermediary cases have been described by vague phrases such as "the majority," "many," "some," and "few." In a number of cases it was difficult to work out any definite classification of opinions and far more fruitful to outline analyses of the relationships between individually stated opinions. Adequate surveying was also made difficult by the fact that hardly any of the thirty questions of the questionnaire were given explicit answers by *all* the contributors. For several questions, so few answers were found in the material that it was thought advisable to pass them by in the survey.

It should be borne in mind that the analytical survey given below sets itself the task of taking into account opinions expressed in *all* the direct contributions received: it will not be confined to those published in the UNESCO volume. For reasons of space as well as to avoid repeating similar views, we could not print all the material: a selection had to be made. This survey may serve to remedy to some extent the inevitable shortcomings of a selection of this nature by supplying direct or indirect accounts of the ideological opinions and the philosophical analyses of a number of the scholars and experts whose contributions could not be printed in the UNESCO volume.

DEMOCRACY, IDEOLOGY, AND RATIONALITY

The publication of a volume of this kind will serve the purpose of acquainting a wider public with the complexity and diversity of ideological thinking. In the existing literature on the controversies on "democracy," only rare and unsystematic attempts have been made at comparative analysis of opinions held on the precise issues into which the general problem can be broken down. The UNESCO questionnaire has served to press the argumentations of the opposing parties into common or nearly common thematic channels and thus made a comparative survey possible.

The aim of the ensuing account is to trace the outlines of such an analytical survey of agreements and disagreements explicit or implicit in the material at hand.

The analysis will make it abundantly clear how desperately difficult it is to compare ideological patterns of argumentation in terms of theoretical agreements and disagreements rather than in terms of historical affiliations or concrete political antagonisms. By stating these difficulties in a frank and intellectually honest way, I hope that the analysis may serve to counteract tendencies toward ideological black-and-white thinking and toward propagandistic oversimplification of the issues. In this way, painstaking analysis of ideological opposition may serve the purposes of UNESCO by counteracting tendencies to obscure whatever is common to the doctrines of conflicting groups. An important step toward world understanding might be achieved through concerted action to thwart the effects of the kind of ideological thinking and propaganda that tends to exalt existing antagonisms beyond all possibility of settlement.

The classification of opinions expressed in the material under scrutiny has proceeded from the tentative assumption that ideologists mean what they say: that when someone expresses an opinion as his own, he has that opinion. The possibility that he lies—deliberately or unintentionally—is not discarded by this tentative assumption, but the assumption serves the pragmatic purpose of counteracting any tendency to succumb to the temptation of interpreting and classifying ideologically opposed statements so that they fit into preconceived and stereotyped pictures of the antagonism. The aim is to analyze controversies, not to continue them. One way to achieve this end is to classify statements at their face value. That is what has been attempted in the ensuing survey.

The obvious objection to the adoption of an initial assumption of this

kind is that no understanding of conflicts can be achieved without an analysis of the *motivations* of the statements from opposing camps, without an analysis of what is *really meant* and *really wanted* by those who use ideological concepts and appeal to ideological principles and ideals: it is such a trivial truism that people may really want and mean the very opposite of what they appear to say.

Nevertheless our tentative assumption can be upheld, and for three reasons at least:

1. What people say is, after all, one important symptom of what they “mean”: any opinion leader attacking ideological opponents will easily deceive his audience if for each statement he does not make it clear whether he is describing what his opponents say they believe or what he indirectly infers that they “really” believe.
2. Any one of us who has honestly tried to compare the doctrines of his own group with those of his opponents will have to admit how much harder it is to apply the brutal tools of motivational analysis to our own rationalizations, hypocritical appeals, and tacit assumptions than it is to those of our ideological opponents. Deeper insight into the intricately biased character of current imputations of “real” meanings and motives may result in valuable attempts to treat ideologically opposed doctrines on an equal footing, either by subjecting both to the same rigors of motivational analysis or by taking the more lenient approach of analyzing both in their surface expressions.
3. Even if we can prove that the opinion leaders of our ideological opponents hold doctrines very different from those they say they hold, there may well be large masses among their followers who believe just as sincerely in their expressed doctrines as we believe in our own. Uncritical emphasis on motivational analysis may therefore serve to strengthen the widespread ideological tendency to picture opponents as a homogeneous mass manifesting the same evil traits that have been imputed to its ruling group.

It goes without saying that this argumentation in favor of a comparison of expressed doctrines does not imply any depreciation of efforts to go

beyond the verbalized reactions of human beings. However, the comparative analysis of expressed doctrines is an important initial phase in ideology research. The material under scrutiny does not allow us to go any farther in this analysis: the study of the behavioral correlates and the social and historical settings of ideological controversies will have to be based on broader foundations of theoretical inquiries, historical investigations, and experimental research.

The Semantics of *Democracy*

Is the Term Democracy Ambiguous?

From the very outset of this inquiry nearly every one of those who discussed the matter seemed to expect universal agreement among the experts consulted on the first of the questions in the questionnaire: they were all expected to answer that democracy is ambiguous. A survey of the actual answers, however, reveals that they did not. A few of the contributors expressly deny that democracy is an ambiguous term. Several others attribute to it an unambiguous core of meaning unaltered throughout its usage in historically and geographically varied contexts. The majority of the contributors, however, expressly affirm the ambiguity of democracy. It is true that the introduction to the UNESCO document and the very wording of the question may have led a number of them to adopt this view without critical scrutiny, but that is a matter that will have to be left to conjecture.

One outstanding reason for the discrepancies in the reactions to the ambiguity question must be sought in the imprecision of current semantic terminology. Only crude beginnings have been made toward critical assessment and theoretical integration of basic concepts in semantics. Current usage of terms like *meaning*, *definition*, *synonymity*, and *ambiguity* is so vague that agreements as well as disagreements of a purely verbal character are constantly apt to crop up. There is no semantic highway opened up anywhere to the clarification of ideological disputes: rigorous analysis and codification of the theoretical structure of semantics and the logic of concepts and definitions will have to precede any successful attempt in this direction.

As used in the UNESCO document, the word *ambiguity* easily lent it-

self to divergent interpretations. There is ample evidence that the respondents did not all understand the word in the same way. The disagreement registered between respondents affirming and respondents questioning or denying the ambiguity of democracy may not necessarily have reflected ideological or theoretical discord but simply a difference in interpretation and usage: the disagreement might not have emerged at all if the question had been given a more precise formulation.

Those who deny the ambiguity of the term *democracy* do not therefore deny divergencies in its usage; on the contrary, they all expressly affirm that the term has been used in different ways in different contexts by different groups. That the word *democracy* is used in different and occasionally incompatible ways is not questioned by anybody. What is questioned is whether these divergences of usage constitute ambiguity and whether they are at all relevant to the determination of the meaning or meanings of democracy.

Several of those who entered upon an analysis of this problem have taken a stand for strict separation of meaning from usage.

Risieri Frondizi² takes the view that the word *democracy* is neither ambiguous nor unambiguous per se; it is only its usage that is ambiguous. An almost identical assertion is made by C. J. Ducasse,³ but perhaps for very different reasons. Statements by D. Brown, Charles Eisenmann, and Gunnar Heckscher seem to go in a similar direction.

How, then, is the meaning of the word to be determined if its actual usage is not to be taken into account?

A number of respondents simply postulate one sense as the only legitimate one, as the intrinsic, strict, or correct sense: actual usage may deviate from this sense but cannot alter it.

Thus, C. I. Lewis does not think that *democracy* is more ambiguous than most words in "its first, literal, or strict meaning": "All will agree that strictly it applies to any political regime in which the sovereign power is vested in the people at large, and that it applies to no other."⁴

Henri Lefebvre does not think there is any ambiguity in the concept of democracy: "Democracy clearly implies justice, liberty, order, progress, reason, fraternity, and a living community of individuals within the nation."⁵

Barna Horvath identifies democracy with "good self-government": "government by unanimous decisions proved to be good and useful to all."

This general sense of the term is stated to be perfectly clear and entirely free from ambiguity.⁶

Other respondents are equally bent on finding a central formula for the fundamental meaning of democracy but take greater care to determine the relation of this meaning to the traditions of usage.

Thus, Richard McKeon does not consider democracy ambiguous "in the sense that many different formulas have been proposed to define its meaning, but in the sense that many different interpretations have been proposed and elaborated for a formula on which there has been remarkable continuity of agreement. . . . Very few discussions of democracy, adverse or favorable, would be distorted in interpreting 'democracy' as the rule of the people in their own interest."⁷

Limiting his discussion to the nineteenth and twentieth centuries, John Petrov Plamenatz is convinced that implied by practically all serious statements that communists as well as liberalists have made about democracy is a primary meaning he thinks can be roughly defined as "government by persons who are freely chosen by and responsible to the governed."⁸

Going all the way back to Greek origins, G. C. Field thinks there is "overwhelming evidence" that traditional usage bears out a similar definition: "A state is democratic . . . in so far as the whole body of citizens . . . exercise an effective influence on the decisions of government."⁹

Jørgen Jørgensen discerns a far more general core meaning through the variations of usage and application: to him, democracy should be equated with "a general process of liberation and equalization" in all areas of human life.¹⁰

All those who have thus tried to formulate what in their opinion is the fundamental meaning of democracy have immediately felt themselves confronted by the problem raised by current ideological controversies over this keyword: Why the divergencies in usage despite the unity in meaning? Why the disagreements in interpretation despite the agreement in definition?

Solutions of the kind suggested by McKeon are explicitly or implicitly accepted by a number of respondents; agreement can certainly be reached on a central formula defining a basic concept, but disagreement will arise as soon as the different elements of the formula have to be interpreted in and applied to concrete social and political situations.

Chaim Perelman amplifies this approach by analyzing the possibilities of establishing a “normal sense” of the term: attempts might be made to arrive by way of inductions from empirical investigations at determining a structure common to all historically known usages of democracy. An empirical definition of this kind might take the form of a propositional function of one or more variables: agreement might then be possible on the structure of the function while controversies would continue on the value of the variables. It might, for example, very well be possible to define democracy as “government for the equal welfare of all as determined through the free decisions of all”: the only advantage, if any, would be to have transferred the focus of controversy from “democracy” to “welfare,” “equality,” and “freedom.”¹¹

Several respondents go into further detail in explaining the relationship between the fundamental meaning and the divergencies of usage.

Horvath, Lefebvre, Plamenatz, and Heckscher, however different their approaches may otherwise be, can all be classified as taking the view that the general meaning of democracy is as clear and free of ambiguity as ordinary language permits: it is the expression of an ideal, a standard, and a goal, a reflection of human aspirations. Ideological disputes do not arise from disagreements on this general meaning and the ideal type of human relationship it expresses: the disputes concern the conditions that make for progress toward the ideal, the means by which it can be reached, the order of measures to be taken in developing it. As a consequence, current ideological controversies do not center on the meaning of democracy but on theories of the conditions of its growth and the means of its accomplishment; what stands opposed are not analytical statements of definitions but synthetic statements of social and political interrelations. Accusations of ambiguity and misuse arise from unconscious confusions of means with goals as well as from deliberate attempts to identify accomplished conditions with the general ideal.¹²

The difficulty inherent in this kind of approach is that in actual practice it is very hard to reach agreement on what is end and what is means, what is ideal and what is accomplishment. Ideological statements constantly oscillate between analyticity and syntheticity, between the expression of the meaning of words and the formulation of empirical relationships between the matters denoted by the words. Statements about what

“democracy demands,” what “democracy implies,” what “democracy means” may be interpreted either way: what one party may question as a possible condition of democracy may be taken as an essential element of its concept by the other party.

Lewis seems to find the reasons for the ideological disagreements in a process of a similar kind when he states that although the primary meaning of democracy is clear and simple, controversies over its meaning will arise “because different parties wish to require further characteristics of anything they will allow to be called a democracy, and because they disagree as to what further characteristics are to be so required.”¹³

It may be inferred that a number of the respondents disagree with this view, partly because in actual practice the “strict” definition given by Lewis will turn out to admit of a great variety of interpretations, partly for the reason that a line cannot easily be drawn between a strict primary sense on the one hand and incompatible ideological uses on the other. The contradiction between the positions taken by Jørgensen¹⁴ and Alf Ross¹⁵ goes to show how mutual charges of ideological exploitation can be leveled even at attempts to formulate strict primary meanings.

In a short letter on this matter, Charles L. Stevenson suggests an approach that ought to inspire further elaboration: it merges into one model most of the elements introduced into the discussion of the ambiguity question by other contributors. To Stevenson, current ideological usage of *democracy* is characterized by multidimensional ambiguity. However used, the term covers complex concepts analyzable into a number of factors expressive of indexes or criteria of “democraticity”: the term is never ambiguous or vague in one respect only, but in several. The indeterminacy of its reference can be traced down to a number of reasons: (1) there is no agreement on the criteria to be included in the concept, (2) there is no agreement on the relative weight to be given each criterion, (3) there is no agreed-upon line of demarcation between “democratic” and “nondemocratic” on the theoretically possible scales that may be constructed to determine the degree to which each criterion is fulfilled.

The short formulas suggested by a number of contributors may serve to express opinions on the first point: the choice of criteria to take into account. Formulas emphasizing the political core of meaning will imply concepts based on criteria such as percentage of population having access to in-

fluence on government decisions, degree of independence of popular opinion formation, directness of popular influence, and revocability of mandates and decisions. Other formulas might give further emphasis to less clearly political criteria: equal distribution of economic benefits, equality of social status, degree of legal security, absence of discrimination, and so on. Others again may indicate concepts of an exclusively economic, social, or way-of-life character, thus opposed to the predominantly political concepts. Stevenson's main point, however, is that even if agreement were reached on the choice of criteria, democracy would still be multidimensionally ambiguous because each concrete application of the criteria would be indeterminate and a potential source of violent controversy: What relative weight should be given to each criterion? What scales of measurement or comparison should be chosen to determine the degree of fulfillment of each criterion? Where on each scale should the line be drawn between "democratic" and "nondemocratic"?

Several other contributors have stressed the impossibility of establishing strict lines of demarcation. Field, Horvath,¹⁶ and A. C. Ewing all maintain that in concrete cases no clear-cut distinctions between what is democratic and what is not democratic can be made; it is all a matter of degree, of more or less. Ewing states that "strictly speaking, we should talk, not of democracies, but of a democratic element in states." Statements of this kind must not be construed to imply indifference to democratic ideals. The point has been admirably put by Field: "On the other hand, there is, of course, no reason why we should not continue to speak, roughly, of one state as democratic if it has a considerable degree of democracy, and another as undemocratic if it has very little or hardly any at all, in just the same way as we speak of the weather as warm or cold, though we could not fix an exact point on the thermometer at which one ended and the other began. But we must not fall into the blunder, either, with regard to democracy or the weather, of speaking as if a difference of degree was not important. The phrase 'It's only a difference of degree' is nearly always a mark of political illiteracy."¹⁷

Ross takes an approach closely similar to that of Stevenson: he suggests the construction of a multidimensional "ideal type" concept of democracy that might serve as the basis for comparative assessments of the degrees of "democraticity" achieved in "real types."¹⁸ Whereas Stevenson is mainly

interested in mapping out the various modes of indeterminacy, though, Ross is primarily concerned with the construction of one working concept. Both attempts, however, point to the need for more painstaking analysis of the elements involved and for greater precision in the formulation of theories of their interrelations in ideological argumentation as well as in sociopolitical reality.

The majority of the respondents do not enter into any detailed analysis of these problems. A great number affirm the existence of incompatible usages of democracy and refrain from attempting to single out any one of them as the "correct" one, the "primary" one, or the "strict" one. Among those who take this attitude are Charles Bettelheim,¹⁹ Humayun Kabir,²⁰ Lord Lindsay of Birker,²¹ Perelman,²² Ithiel de Sola Pool,²³ Wilhelm Röpke,²⁴ Paul M. Sweezy,²⁵ George Boas, Ture Nerman, Svend Ranulf, and T. V. Smith. Arthur Lovejoy does not hesitate to characterize democracy as one of the most ambiguous words in current use.

It should be emphasized that respondents who thus affirm the existence of incompatible usages do not thereby deny the possibility that the usages may have common characteristics; but they do not think that these common traits suffice to make up a useful concept of democracy. Neither does the affirmation of equally valid but incompatible usages exclude the justification of proposals for the discontinuation of some of the usages. It does not even preclude the possibility of characterizing one or more of the usages as misuse in the sense of their being potential tools of deceit.

Complications of this kind have to be faced by anyone wishing to obtain clear-cut evidence of ambiguity. The question arises, What practical criteria are used by ideologists to identify cases of ambiguity? The second question in the questionnaire was formulated in the hope that respondents might quote different occurrences of the term *democracy* in historically given ideological texts and state their reasons for referring to one occurrence as an instance of one sense of the word and another occurrence as an instance of a second sense, incompatible with or at least divergent from, the first.

Evidence of Ambiguity

To any analyst interested in the elaboration of reliable procedures for the determination of minute as well as wide differences in usage, answers to the

second question must be said to have been disappointing. The majority of respondents did not think it at all necessary to corroborate their affirmations of ambiguity with arguments from historically given occurrences of democracy: they either stressed the superfluity and futility of searching for evidence for such an obvious fact or they considered the UNESCO inquiry and questionnaire alone sufficient proof of the ambiguity of the word. Although a small number of contributors—Jørgensen,²⁶ McKeon,²⁷ Ross,²⁸ Oliver C. Cox, J. M. Hagopian, Ranulf—took care to list a number of examples of what they considered usages sufficiently divergent to establish ambiguity, the difficulties involved in establishing rigorous criteria for the identification of cases of ambiguity were not explicitly discussed by anyone except David van Dantzig.²⁹ In assessing the relevance of the quoted occurrences to the determination of ambiguities, two points should be kept in mind:

1. The fact that ideologist *A* calls democratic a state that ideologist *B* violently rejects as undemocratic does not exclude the possibility that they both use *democracy* in the same sense; the disagreement may owe to opposing *descriptions* of the state in question. If *A*'s description were established as adequate, they might both agree that the state would fulfill the requirements of a democracy; if *B*'s description were established as adequate, they might agree to reject the state as undemocratic. Violent controversies over *democracy* may consequently be possible without any ambiguity in the concept.
2. Ideologist *A* may restrict his use of *democracy* to one kind of structure or relationship whereas ideologist *B* thinks it justified to use the term to characterize a number of other kinds of structures or relationships. This disagreement does not necessarily establish ambiguity, since a wider and more diluted sense may be constructed that is common to all the structures or relationships thus characterized.

To take an example, Ross seems to believe that sufficient evidence of ambiguity is implied in these four occurrences of *democracy* or close derivatives in everyday use: (1) The Danish state is a democracy. (2) This law, which deprives widows of economic support, is undemocratic. (3) The army ought to be democratized. (4) It is undemocratic not to take one's meals with one's servants.³⁰

Everybody will agree that in these four cases *democracy* is applied to very different kinds of structures or relationships. It may be inferred, however, that several of the respondents, and particularly Jørgensen,³¹ would disagree with the implication that this diversity of application establishes ambiguity; *democracy* may very well be interpreted to have been used in the same—although highly diluted—sense throughout the four examples.

The fact that practically all respondents leave untouched the intricate problems involved in establishing reliable distinctions between usages should surprise no one who is familiar with the present predicament of semantics and the linguistics of ideological discourse. As long as no reliable methods have been developed, it is quite understandable that even the most competent experts in ideology research fail to agree on the sense in which *democracy* has been used by the great ideologists of the past; it may not at all be necessary to explain their disagreements by assumptions of political bias.

Is Democracy Misused?

Analysis of the widespread complaints of ambiguity and looseness leads the way to a general discussion of the causes and justifications of the indignant charges of misuse that are so frequently hurled in all directions in current ideological conflicts.

This is a problem that seems to have attracted the attention of a greater number of respondents than most of the other questions on the questionnaire. A considerable number of contributors try to give explicit formulations of their criteria of misuse. Fairly thorough analyses of concepts of misuse are given by van Dantzig,³² Ducasse,³³ Jørgensen,³⁴ Lewis,³⁵ I. M. Bochenski, and Lovejoy. A comparison of the definitions arrived at will illuminate the terminological difficulties involved in the clarification of ideological controversies.

Ducasse works out a definition of misuse that furnishes a fruitful point of departure: "Misuse of a word is provable if either: (a) A definition of it is agreed upon, but the concrete things to which the word is then applied lack some of the characteristics specified in or implied by the agreed definition. This is misuse in the sense of misapplication. (b) One or more concrete things are agreed upon as being ones to which the word shall be applied, but

the word is then applied to connote one or more characters not in fact possessed by all the concrete things agreed upon as the ones to which the word shall be applied. This is misuse in the sense of mischaracterization.”³⁶

Ducasse is well aware of the difficulties involved in concrete applications of these criteria. The likelihood of agreement on denotation is just as small as the likelihood of agreement on connotation. An essential part of ideological controversies is focused on disagreements on the characters “in fact possessed” or not by such and such “concrete things.” What is the character of the state of affairs in the United States or in Soviet Russia? Charges of misuse in the Ducasse sense would be justifiable only on the assumption of agreement on descriptions of states of affairs of this kind: a highly unrealistic assumption as far as ideological controversies are concerned.

Bochenski introduces several additional elements in his definition of misuse: there is misuse if and only if (a) the word *democracy* is used in a sense *A* in addressing a public that understands it in a sense *B* different from *A*, (b) the public so addressed resents the shift in meaning from *B* to *A*, and (c) the state of affairs referred to by sense *A* is associated with negative value judgments, while the state of affairs referred to by sense *B* is associated with positive value judgments by the public addressed.

The important factors in this definition are the difference between sender use and receiver interpretation, the valuational relevance of the shift in meaning, and the relativity of misuse to the attitudes and moral dispositions of the public addressed. The definition does not require that the public has been actually misled by the shift in meaning: it is enough that it resents the shift.

The definitions introduced by van Dantzig,³⁷ Jørgensen,³⁸ Lewis,³⁹ and Lovejoy all give particular emphasis to the deceit factor: charges of misuse involve moral indignation at attempts to mislead audiences to accept opinions or adopt attitudes on false premises.

Lovejoy formulates a definition of this kind in the following way: “I should define the ‘misuse’ of a term as its use in such a manner that it is certain, or highly probable, that it will not be understood in the same sense by the readers and hearers as by the writers or speakers, but will nevertheless predispose the former to a favorable attitude toward the ideas favored by the latter, or lead to actual confusion of the two senses of the term.”

In this view, the use of value-loaded words with unstable cognitive con-

notations is a powerful tool of attitude influencing and control. The use of words of this character is an integral part of ideological persuasion processes: the very act of branding some usage correct and others misleading is a step in the process. Van Dantzig, Jørgensen, Lewis, James Marshall,⁴⁰ Perelman,⁴¹ Pool,⁴² Ross,⁴³ and the authors of the memorandum submitted by the International Society for Significs have given particular emphasis to this persuasive function of statements on democracy and its "misuse."⁴⁴

Some disagreement seems to exist on the question of whether charges of misuse should be focused on the actual act of using the keyword in a sense different from the one apt to be understood by the audience, or on the deceitful motive of misleading the audience by effecting a shift in meaning. Bochenski seems inclined to the former position. So does Marten ten Hoor, who seems to think that misuse can be charged even when the speaker or writer only fails "to realize that there are other meanings of the term than his own." On the other hand, Jørgensen does not think that unconscious or unintentional misleading of this and similar kinds can be charged as misuse: with the meanings of ideological keywords being as unstable as they are, nobody should be charged with, and thought guilty of, misuse unless a deliberate motive of deceit can be established at the basis of the misleading use of the word in question.⁴⁵ In a similar vein, Horace M. Kallen does not think the divergencies of usage can be traced to any kind of misuse unless "insincerity or malice is attributable to the user."⁴⁶ The difficulties involved in the identification of concrete cases of deceitful or insincere motivation have not, however, been addressed by any of the contributors.

The divergencies of emphasis and scope manifest in the definitions of misuse are reflected in one way or another in the disagreements registered in concrete exemplification.

Lovejoy concludes that in the sense he has given the word, "there appears to be extensive misuse of the word democracy nowadays, particularly in the propaganda of the Soviet Union." A considerable number of other contributors make statements to the same effect, waiving, however, qualifications and reservations of the kind indicated by Lovejoy.

Lefebvre states that democracy is being misused by middle-class politicians who mislead the people by trying to let their bourgeois democracy pass for the ideal democracy—be it from unconscious prejudice or from "a deliberate, cynical determination to bamboozle."⁴⁷

Bochenski stresses the relativity of any justifiable charge of misuse to the language habits and expectations of the group addressed: "Any man using the word democracy in the current Russian sense in addressing a Western audience misuses the word just as much as anyone using it in the Western sense in addressing a Russian audience."

A considerable number of respondents find it hardly justifiable, possible, or meaningful to charge anybody with misuse. Thus, McKeon,⁴⁸ Perelman,⁴⁹ J.W. Gough, Ranulf, and many others emphasize that in the absence of a generally accepted usage taken to define the "correct sense," no misuse can be charged. Others, like Pool,⁵⁰ Quincy Wright,⁵¹ Boas, and G. H. Sabine, urge the conventionality of word-meaning relations and tend to imply that charges of misuse cannot be upheld without inconsistency by those who adopt this view.

It seems plausible to infer, however, that the "misuse" notion repudiated by these two groups of contributors has more in common with the Ducasse concept of misuse than with the Lovejoy concept; they do deny the justification of charges of misuse in the sense of deviation from usage agreed upon as "correct," but they may very well affirm the justification of charges of misuse in the sense of deceitful exploitation of the language habits of the groups addressed. The surface disagreement may thus resolve itself into substantial agreement; this is only one of many cases of this kind that we shall have occasion to note in this survey.

What, then, are the main trends of answers to the question on misuse?

The confusion of terminology and the complex entanglement of issues make most of the answers difficult to compare. Any conclusions on "main trends" will consequently tend to be vague and airy.

First of all, the material at hand gives evidence that charges or denials of "misuse" may have largely divergent meanings even among experts, and that the diversity of meanings is not generally known to them.

Two main meanings of misuse vie with each other in the contributions: one "logical," the other "ethical." In the first sense, there are charges of misapplication and mischaracterization without any necessary moral relevance. In the second sense, there are charges of deceitful manipulations of meanings in processes of persuasion—charges with ethical implications just as pronounced as those applied to lies and fraud.

Practically all the contributors would agree that *democracy* is being mis-

used in the latter sense, but opinions differ in the concrete attribution of guilt: which ideological groups are most addicted to misleading use of the keyword *democracy*.

On the questions of misapplication and mischaracterization, considerable disagreement is evidenced. Some respondents seem to favor the assumption that a definite sense, a “strict,” “correct,” “real” meaning of *democracy* can be established and formulated; all use deviating from this meaning is automatically “misuse.” Other respondents deny the possibility of singling out any such “correct” meaning and the existence of any universally accepted meaning; this they take to imply that no “misuse” of *democracy* is possible or chargeable—at least in the “logical” sense of deviation from “correct” use.

Confronted with this complex and confused picture, the analyst can only conclude that mutual charges of misuse cannot contribute to the clarification of ideological disputes—at least as long as in each case the criteria of misuse adopted are not explicitly formulated and empirical evidence is not proffered to substantiate the assumption that the criteria are fulfilled.

Aspirations Versus Achievements

Why is so much indignation focused on the terminology used in ideological disputes? One of the reasons has been sought in the frustrations experienced through constant misleading use of keywords: this subject has already been dealt with. Another reason may be sought in the frequent confusion of facts and ideals manifest in the use of keywords in ideological defense as well as attack: *democracy*, for example, may oscillate between denoting an established power structure in a society and connoting the ideal limits toward which the society strives to develop. Some of the violence of controversies and some of the indignation at ideological terminology may be traced to the mutual misinterpretations caused by this oscillation:

1. Our own high-pitched proclamations for democracy will tend to be interpreted as out-and-out praise for our status quo by our ideological opponents, whereas we—at least upon closer analysis—would reluctantly concede that our enthusiasm was largely directed toward characteristics so far not realized in our country.

2. Inversely, our criticism of the undemocratic character of an ideologically opposed people is by them interpreted as an attack on their cherished democratic ideals, whereas in fact our criticism was limited to the actual degree of achievement of those ideals in the rival country.

One of the questions⁵² in the UNESCO document focused on misinterpretations of this kind: it asked whether the confusion of ideals with actual conditions was apt to increase the violence of discussions.

The majority of the relatively few who discussed the matter gave affirmative answers to the question, thus Ducasse,⁵³ Horvath,⁵⁴ Jørgensen,⁵⁵ Gough, Heckscher, Nerman, S. V. Puntambekar, Ranulf, Emil J. Walter.

Lovejoy tries to determine in a more precise way the conditions for an increase in ideological violence. His brief remarks may be construed to indicate the following possibilities: (1) if everybody is confused about the meaning of the term, no increase is likely; (2) if one party is aware of the distinctions but believes that the other is trying to mislead by its ambiguous use of the term, increase is likely; (3) if both parties are aware of their equal immunity to terminological misleading, a truce may take place or new strategies develop.

McKeon takes the view that "the violence of controversies seldom results from the confusion of ideals with actual conditions": far more active as causal factors are disagreements on the character of the imperfections and the means to remove them.⁵⁶

The problem of the causes making for violence in ideological disputes is an empirical one that will have to be settled by investigations within psychology, sociology, and political science. The suggestions made in the UNESCO document and the answers given by contributors largely reflect intuitive opinions on the choice of therapeutical procedure in assuaging controversies.

New Uses

All questions that have been raised in order to throw light on the terminological tangles around the keyword *democracy* lead up to one that cannot be

answered without painstaking research: what can historical studies of the development of usage contribute to the clarification of the controversies over the “meanings,” “ambiguities,” and “misuses”?

Most of the contributors did not have time to concern themselves with historical questions. Those who gave them more than passing attention are easily counted: M. M. Bober on the usage of Marx and Engels, McKeon on the relation between conflicts found in classical and modern uses, Stanislaus Ossowski on bourgeois versus socialist uses, Plamenatz on Marxian-Leninist usage, Pool on the development of the split between Western and Eastern usages, Rudolf Schlesinger on Soviet usage, and Sweezy with remarks on the history of socialist usage. The conclusions arrived at in these studies cannot be surveyed in this context.⁵⁷ Suffice it to say that they reveal deep-rooted disagreements, which can be settled only by patient and detached research on a much larger scale than any so far undertaken.

The focal point of interest was, as might have been expected, the historical relationship between the liberalist-Western usage and the communist-Eastern usage. In the UNESCO questionnaire⁵⁸ the question was raised of whether any of the current usages—and it was apparent that the East-West split in usage was being referred to—could be considered “new” in relation, for example, to nineteenth-century or prewar usages. The question was deliberately left vague in order that respondents might be provoked to develop their views at greater length. Even though only a few could take the time to do so, a considerable number of others expressed fairly definite opinions on the subject without taking any great care to document them.

Practically all those who find that new usages have emerged in the twentieth century locate the main innovations in the usage of revolutionary Marxists and particularly in that of the ideologists of the Soviet Union and the popular democracies of Eastern Europe: thus Ross,⁵⁹ Brown, Heckscher, Nerman, Puntambekar, Ranulf. A few also consider usages stressing the social and economic content in general as “new” in relation to nineteenth-century use. It is quite apparent that the charges of innovation are closely correlated to general charges of misuse.

On the other hand, a number of respondents of divergent ideological affiliation take the view that both of the current major usages can claim ample historical justification: thus Lindsay,⁶⁰ McKeon,⁶¹ Stanislaus Ossowski,⁶²

Plamenatz,⁶³ and Paul M. Sweezy.⁶⁴ The position taken by Pool is slightly more sophisticated; both current usages are innovations in relation to the “classical” usage prevalent in Europe and America until about 1848.⁶⁵

The material at hand cannot support any positive conclusions one way or another. Further research is of importance for efforts of clarification and reconciliation, because arguments from the history of usage play active parts in controversies over “right use” and “misuse”: theories of terminological innovation support claims that usages have been deliberately coined in order to confuse and profit from the confusion. Research may show that the development of the use of *democracy* is too complex and many-sided to justify any monopoly of the term in favor of any particular ideological group. It is not, however, the task of the present analysis to conjecture what results further research will yield.

Common Characteristics

As a direct sequel to the question on the historical basis of current usages, the UNESCO questionnaire takes up for scrutiny the widespread opinion that the meaning of *democracy* cannot be understood in abstracto, but only in its historical relations to concrete social and political structures that have been classed as “kinds” of democracy. The question was asked whether these historical structures have any characteristics in common that make them democracies.⁶⁶

Answers to this question present a muddled picture because it is rarely clear exactly which of the many interpretations of the question the respondent has focused on.

Everybody agrees that *democracy* is not a proper name for one unique structure but a term that can be applied to structures that, although similar in a number of features, may well differ to the point of incompatibility in others. There is disagreement, however, on the range and extent of application of the term; thus, some do not think it is properly used in the phrase *Athenian democracy*, others would not class “bourgeois democracy” among democracies, and still others think that “Soviet democracy” is a misnomer, since in their opinion the Soviet regime is a dictatorship.⁶⁷

The majority of answers, however, express the opinion that all historically given democracies have common characteristics. It is true that these

characteristics are not always held to be common to all structures that have ever been called democratic but only to those that have "properly" been so called. Thus, Lewis states: "Insofar as all are truly democracies, they have in common two characteristics: (1) sovereignty is vested in the general will of the people, and all of them equally; (2) the government is such that it is a rule of laws and not of men."⁶⁸

Most of those who affirm the existence of common characteristics do not make any such reservations, however. Nevertheless, their formulations of the characteristics reveal very wide differences of scope and emphasis.

To James K. Feibleman, the different "kinds" of democracy have nothing in common but a common misuse of the term *democracy*. To Max Nomad, their only common characteristic is the fact that they all claim to be representative of the will of the people. Other contributors are more specific in their formulations of common characteristics. Charles Bettelheim takes the view that, although each democracy has to be judged in its historical context, they have at least one characteristic in common: that each, at its particular stage in history, represents an attempt to reduce to a minimum the scope and intensity of social coercion. Kabir finds a common characteristic to "all the different political systems and ideologies which we call democratic" in "the urge to establish an equivalence if not an identity" between duties and rights.⁶⁹ Gough finds that there are common exclusions: hereditary privileges, racial discriminations, and so on. McKeon⁷⁰ goes into further detail: "All democracies have in common (1) political institutions designed to make effective the will of the people in the regulation of the common life, without discrimination, of all the people, and (2) provisions in the organization of these institutions to protect against arbitrary action, by such devices as the protection of human rights and the promulgation of a rule of law."

The problem of whether the structures referred to by current Western usages have anything in common with the structures referred to by current Eastern usages is dealt with at greater length than any other.

Ossowski⁷¹ emphasizes the historical community of values that exists between the two conceptions. Similar views are taken by Horvath,⁷² Jørgensen,⁷³ Marvin Farber, and Arnold J. Lien. The material does not, however, furnish any detailed analysis of the individual characteristics thus deemed common to the two kinds of structure. There is approximate unanimity that such common traits exist, but the ones on which there is most

widespread agreement are hardly such as to affect the opposition of valuational attitudes toward the two kinds of structures.

Concluding Remarks

What kind of lessons can we learn from the answers to the terminologically centered first part of the questionnaire?

First of all, that there are deep-rooted disagreements concerning matters on which the common man cannot expect to be able to make up his own mind: on the technicalities of semantics, in the descriptions of divergencies of usage, on the history of the semantical fluctuations in the term *democracy*.

Second, that these disagreements among experts in a large number of cases reflect divergencies of ideological bias. There is a manifest tendency to present one's own views as the only ones worthy of serious consideration, whereas those of opponents are more often than not found to contain misrepresentations, distortions, and even deliberate fraud. There is a tendency to picture one's own efforts as serving the purposes of clarification only, while the tenets set forth by ideological opponents are primarily treated as instruments of persuasion adapted to political tactics. There is a tendency to use history as a tool of ideological justification and to affirm the validity of conclusions from historical study in ways more extreme and absolute than are warranted by the meager empirical evidence at hand.

Notable exceptions are to be found in the material, but this is a report on general trends.

The lesson of all this lies in the realization that knowledge of ideological processes is still so little developed that standardized oversimplifications of controversial issues can win widespread acceptance under the shelter of scholarly authority.

The answers to the questions on the semantics of *democracy* furnish excellent illustrations of this predicament: they show how even outstanding experts are apt to treat complex historical, linguistic, and philosophical issues as if there were only a choice between a true account and a definite analysis on the one hand and a heap of crude misrepresentations and deliberate distortions on the other.

Intense analysis and painstaking empirical studies may, if conducted by researchers free of direct ideological entanglements, prove a powerful

weapon against oversimplification and black-white thinking and thus make it harder to appeal to violence on false pretensions. The urgency of an expansion and intensification of ideology research is clearly manifested in the material on the first part of the UNESCO questionnaire.

Political and Other Democracies

The Lincoln Formula

Having in its first part focused on the general linguistic problems involved in current ideological use of the term *democracy*, the UNESCO questionnaire in its second and third parts proceeded to detailed analyses of two of the fundamental issues that were assumed to lie at the root of the intense controversies on terminology: (1) the problem of the relationship between political "democratization" and economic and social "democratization," dealt with in part B of the questionnaire;⁷⁴ and (2) the problem of the right of opposition and the limits of toleration within states to be classed as democracies, dealt with in part C.⁷⁵

None of the respondents has directly criticized this procedure. It is true that there is wide disagreement on the relative emphasis to be given the one and the other cluster of problems, but it seems safe to infer that there is general agreement that both are pivotal issues in the controversies raging in the contemporary world. An extensive survey of current ideological literature seemed to point to the same conclusion.

In its details, however, the UNESCO procedure has occasionally aroused emphatic criticism.

In the second part of the questionnaire, the Gettysburg "of . . . by . . . for" formula was chosen as a tentative point of departure for the analysis of current meanings of *democracy*: provocative interpretations of the three famous prepositions were given, and scholars and experts were asked to work out their comments.⁷⁶

A small but vocal number of respondents resented this choice of approach. Thus, Boas does not think that anything can be cleared up by starting out from a formula that "had an immense emotional force for Americans," but an emotional force that "was in inverse ratio to the clarity of its meaning." William E. Hocking remarks that "Lincoln was not professing to define democracy in his 'of . . . for . . . by' phrase; those who turn it into a

definition must bear the blame of wholly superfluous confusion." Lewis says: "I should interpret Lincoln's Gettysburg address as a tribute to the dead, and not as a political document."⁷⁷

Schlesinger is convinced that the procedure chosen is a highly misleading one as an approach to the analysis of the differences between the Western and the Soviet conceptions of democracy: these differences cannot by any artifice of interpretation be reduced to differences of emphasis on the elements of the Lincoln formula.⁷⁸

However all this may be, the Lincoln formula was chosen as a point of departure because it is still the central slogan of all groups professing their allegiance to "democracy." It has not only preserved its enormous emotional force with Americans and with Westerners in general; it is also constantly used as a formula for defining democracy by ideologists of the Soviet Union and the eastern European states.⁷⁹ In terms of analysis, this means that an inquiry need not start from the mere word *democracy* as a common denominator but can take its departure from the Lincoln formula and proceed to an analysis of the divergencies manifest in interpretations of its elements.

The interpretations suggested in the questionnaire for the *of*, *by*, and *for* relations provoked a considerable amount of disagreement. On closer analysis, however, this disagreement may be seen to be more apparent than real. Opinions differ because they are not answers to the same questions. Part of the discord undoubtedly owes to the vagueness of reference of the question put to the experts: Does it ask for the meaning Lincoln himself may be presumed to have attached to his words? Or does it ask for a general interpretation of how the American public of his time understood the words? Or again, does it ask for the meanings the words may be conjectured to have for the different groups appealing to them in the present age? Distinctions along these lines are generally ignored by the respondents; it is apparent that formulations of the "real" meaning of those historical words are sensed to be of vital importance in ideological persuasion.

In the questionnaire, the *of* relation was provocatively interpreted to indicate "the obedience of the people to the government."

Surprisingly, the majority of respondents seems to have agreed to this interpretation, although rather few state their view on this point explicitly. It seems safe to infer, however, that the word obedience has been taken in a very weak sense by those who have thus agreed to the interpretation sug-

gested: “of the people” is simply taken to mean that what is being governed is the people, that the people are the object of government.

Those who thus accept the “obedience” interpretation of the *of* clause do not thereby take it to express any necessary criterion to be fulfilled by regimes that are to be classed as democracies.⁸⁰ Ross is very emphatic on this point: “The preposition *of* would not seem to indicate anything beyond the bare fact that a government exists; any government is a government of the people. Who else should it govern?”⁸¹

Exactly the same argument is used by Bober,⁸² Perelman,⁸³ and Schlesinger⁸⁴ *against* the interpretation suggested in the questionnaire: if the *of* relation were only to indicate the fact of obedience, it could not serve to distinguish democratic from nondemocratic regimes. Against the diluted “obedience” interpretation, therefore, are pitted interpretations that make of an important index of “democraticity.” Perelman—and with him ten Hoor—takes the *of* clause to indicate that the people are the source of the government’s power, while Bober—and with him Max Nomad—takes the closely related view that the *of* clause means that the government is such that the people desire it and have affection for it. The difficulty with interpretations of this kind is that they tend to make *of* nearly indistinguishable from *by*; this point is particularly stressed by Lewis.⁸⁵

The “obedience” interpretation of the *of* relation may, however, be construed in the more positive sense that the decisions of government are regularly conformed to by the people. Aimé Patri makes a point of stressing this construction by analyzing the distinction between democracy and anarchy.⁸⁶ Sweezy, on the other hand, emphatically denounces the “obedience” interpretation as an attempt to impute to Lincoln a conservative attitude of admiration for “law and order”; instead, Sweezy maintains that Lincoln by “of the people” must have meant “belonging to the people,” emanating from the people, forming an inseparable part of the people.⁸⁷ Commenting on this interpretation of Sweezy’s, Ducasse expresses serious doubt about whether this was what Lincoln meant or his audience understood him to mean.⁸⁸ It may be questioned whether any such search for “real meanings” can contribute to the clarification of the issues involved; it is more important to analyze the persuasive function of imputations of meanings to authority-loaded statements.

In the cases of *by* and *for*, there is little disagreement on the general in-

terpretation of the relations they indicate between people and government; what is vigorously debated is whether both *for* and *by* should count in the determination of what is and what is not democratic. Opinions are almost evenly divided in the material: one group of respondents gives exclusive emphasis to *by* as the essential criterion; another group stresses the equal importance of *by* and *for* in the determination of *democraticity*. Attitudes and arguments on this matter are, however, so closely correlated to those registered on the question of “narrow” versus “broad” usage of democracy that separate treatment does not seem called for.

The “Narrow” Versus the “Broad” Usage

However vague, however laden with emotional associations, the Lincoln formula opens the door to further scrutiny of the role of the keyword *democracy* in current ideological struggles: What is the nature of the disagreements over the relations between the *by* element and the *for* element in the formula? What part do these disagreements play in the fundamental political oppositions of our age?

The division of opinion manifest in our material between adherents of exclusive “by the people” criteria and adherents of inclusive “by *and* for the people” criteria of democraticity reflects an issue of old standing in the history of political argumentation. A great variety of formulations—from terse sloganized catchphrases to complex systems of philosophical reasoning—have been devised to express what is taken to be the crux and essence of this opposition. Formulations have largely varied with political affiliations and ideological proclivities, and rare indeed are the cases in which opponents have been able to agree on any joint description of the opposition between them. In the UNESCO inquiry, this presented a dilemma that had to be faced squarely: the choice was between producing a formula so complicated and studded with reservations as to make it unreadable and indifferent and setting forth a cruder one at the risk of accusations of ideological bias. In the end, a compromise was devised: the opposition was tentatively described as one between a democracy concept “designating methods of decision making” only and a democracy concept “designating conditions and methods as well as results of decision making.” The former concept was then labeled a narrow political one; the latter, a broad socioeconomic one.

Objections to this formulation of the dichotomy took different forms. To several contributors (McKeon,⁸⁹ Ross,⁹⁰ Christopher Hollis, and Walter), the formulation appeared ideologically biased in favor of one camp—the communist camp. Not only does the term *narrow* have derogatory connotations while *broad* has laudatory ones, but the entire formulation seems calculated to leave the impression that the criteria involved in the one concept are engulfed without impairment in the larger concept—an impression the one camp has a vested interest in spreading, the other in combating and stamping out.

In assessing these accusations we must bear in mind that the formulation was set forth in an attempt to urge opinions on central divergencies in trends of argumentation and persuasive appeals, not on differences in application and achievement. It might well be questioned—and the material shows that it has been—whether the opposition thus formulated is the fundamental one in the ideological conflict currently raging between West and East; this, however, is a matter that will be dealt with in a later section.⁹¹ The opposition formulated reflects one of the many aspects of the general disagreement and deserves scrupulous analysis before the inquiry proceeds to further clarification.

A great deal of the debate revolves around the terminological question “Should *democracy* be used to cover the ‘narrow’ or the ‘broad’ concept?”⁹²

A small number of respondents strongly resented this question. There is no “should” about it, says Ducasse.⁹³ The question poses a pseudo-problem, states Sweezy.⁹⁴ The same position is taken by Lewis.⁹⁵ Bochenski is even more explicit: “All questions asking how a word *ought to be* used are without scientific meaning and cannot be answered. All that can be said is how in fact a term is being used by a [logical] class of men k.”

Nevertheless, the overwhelming majority of respondents does not hesitate to announce how *democracy* should be used; a large group favors the narrow use, but an almost equally large group comes out for the broad use. How are we to explain this striking opposition of reactions to the terminological question? A fuller restatement of the positions taken will show that the opposition is very far from being irreconcilable; the issue seems to turn on the interpretation of *should*, the minority taking it in an absolutistic sense close to its use in moral discourse, the majority in the pragmatic sense of recommendation and advice. The two positions can be outlined as follows:

1. To legislate, moralize, or dictate in matters of terminology is futile and nonsensical. There is no usage such that it *intrinsically* should or

should not be followed. There is no court sanctioning the observation of terminological norms. It is futile to press for terminological uniformity if there are groups that have vested interests in the continuation of existing usages, however heterogeneous. The ethos of science and the honesty of communication demand that current usages be carefully kept apart and specifically labeled; there is no justification for terminological *Gleichschaltung*.

2. It makes sense to recommend or discourage usages; terminological advice can be based on considerations of economy and efficiency of communication, stabilization of expectations, avoidance of frustrations, and so forth, and is just as open to rational argument as most advice on problems of interpersonal behavior. Moreover, attempts to influence and change the usage of others are very far from futile; they make up a normal element in communication processes.

In the material under scrutiny, the arguments used to justify preferences and recommendations in the choice between the two usages of *democracy* can be classified as follows:

- 2.1. If two usages of the same term are found side by side and the one covers a more precise concept, the other a more confused one, the former usage is to be preferred and recommended for general adoption while the latter is to be rejected and its further application discouraged.
- 2.2. If the one is already established in technical discourse among scholars and experts and has been found to serve a useful cognitive purpose, whereas the other only prevails in popular parlance and has never been adopted in any field of systematically organized knowledge, the former is to be preferred for general application while the latter is to be eradicated.
- 2.3. If the one usage defines a concept bringing together closely interdependent elements sharing significant features whereas the other isolates one or a few of these elements from the others and thus diverts attention from what they have in common, there is reason to adopt the former usage and reject the latter.

2.4. If a usage can claim a representative history judged by the length of time since its emergence and by the authoritative status of its users, its continuation is justified.

2.5. If a term is heavily loaded with positive emotional associations, any attempt to use it in any but its “strict,” “original” sense should be banned; the newly coined usage serves as an ideological tool of deceitful persuasion by effecting a transfer of favorable attitudes evoked by the term to objects, conditions, and actions that do not deserve them.

None of these arguments are, of course, very clear-cut: there is disagreement not only over their tenability but even more so over the relevance of their application in concrete cases. In the answers to the terminological question on *democracy*, arguments 2.1 and 2.2 are almost invariably used to justify preference for or recommendation of the “narrow” usage; argument 2.3 usually serves the cause of the “broad” usage; and arguments 2.4 and 2.5 are just as often used in favor of the one as the other usage.

Argument 2.5 is naturally the most malleable of all. To a number of those who are convinced that the narrow use is the “strict” and “original” one, all broader uses stand condemned as cunning attempts to usurp the traditional goodwill acquired by the term *democracy*. Adherents of the broader usages do not hesitate to return the charge; the narrow usage serves propagandistic purposes insofar as it bolsters attitudes of complacency with the status quo of the political setup and impedes the progress of reforms in socioeconomic conditions.

Jørgensen, accordingly, rules out arguments of the 2.5 group as cutting both ways: “There is no reason why the proponents of the narrow political concept should have a monopoly on the positive charge that for a long time already has made *democracy* a most valuable tool of persuasion. By reserving the word for the narrow concept they exploit for their own purposes the traditional goodwill it has acquired. Their reproach that the broad use is propagandistic can be countered by the argument that the narrow use is just as propagandistic in its effects.”⁹⁶

On the whole, when debated on a level of philosophical detachment, the opposition between “narrow” users and “broad” users does not seem so trenchant as is generally assumed. Even the staunchest protagonist of the

strict technical use will admit that as used by a larger public the word will always tend to evoke associations and expectations far beyond what would be warranted by its definition as a narrow concept. Inversely, the advocate of the broad usage will generally concede that within limited contexts the narrow usage may have its cognitive advantages. Both will admit that usage preferences will depend on circumstances; factors such as audience expectations, fields of application, and purposes of communication will all have to be taken into account. The material at hand does not give reasons to believe in the existence of irreconcilable antagonisms on the terminological issues; the majority seems to attach importance to them less for their own sake than as reflections of the more deep-rooted theoretical and normative conflicts.

Mediating efforts are not lacking in the material. A number of respondents think that both usages can claim ample justification: thus Horvath,⁹⁷ H. A. Logemann,⁹⁸ Ossowski,⁹⁹ Sweezy,¹⁰⁰ Eisenmann, Farber, Herbert W. Schneider, and several others. They do not think that there is any reason to give the one usage preference over the other as far as cognitive usefulness is concerned. Neither do they think that appeals to history can tilt the scale one way or the other. There is no sense in monopolizing the term for one of the established concepts.

This does not mean that they advocate obedient conformity to the terminological status quo, but they take the view that the growing public awareness of ambiguities and divergencies in usage will gradually force ideologists and opinion leaders to refine their terminology; the isolated use of *democracy* will decrease and a differentiation of conceptual expressions will take place through specification by adjectives and indexes and through explication by more complex formulas. *Democracy* will then gradually cease to have a cognitive meaning of its own: it will only serve as an element in longer phrases designating the different concepts it has come to suggest.

This process is already well under way in both of the major ideological camps. Ossowski is particularly emphatic on this point. In his view, *Western democracy* and *popular democracy* are both integrated terms that have meanings independent of what *democracy* used in isolation may mean; the two do not designate species of some genus because the sense of the element *democracy* varies with the adjectives prefixed to it.¹⁰¹

A process of this kind will naturally lead to differentiations far more refined than the one suggested in the UNESCO questionnaire between a

“narrow” and a “broad” concept. The very formulation given for the broad concept invites further differentiation. Concepts of *conditions* of decision making may be differentiated from concepts of *methods*. Concepts of *methods* of decision making may again be differentiated from concepts of *contents*.¹⁰² A number of “narrow” concepts may thus be constructed and in their turn combined into “broad” concepts differentiated by the relative weight given to the criteria they engulf. This analytical process will, however, automatically lead away from considerations of terminological niceties to inquiries into the actual and potential empirical relationships between the factors isolated or combined in the concepts thus elaborated.

Political Democracy and Social Democracy Compared

The relations singled out for scrutiny in the UNESCO questionnaire were (1) those between conditions of decision making and methods of decision making, and (2) those between methods of decision making and contents of decisions made.

A number of respondents emphasize the practical and theoretical difficulties of keeping apart aspects that are so closely interrelated in one continuous process, but the majority of the contributors seem to agree on the heuristic value of the distinction made among conditions, methods, and contents of decision making.¹⁰³

All three factors play important parts in current ideological use of democracy. Schematically, their relations may be outlined in this way:

Does “democracy” require the existence of established methods for popular control of governmental decision making? It may be inferred that practically all respondents answer yes to this question.

Does “democracy” require the existence of conditions making for independence of opinion formation affecting the efficiency of these methods of popular control? To this, most respondents answer yes, but there is pronounced disagreement on the nature and scope of the conditions thus required.

Does “democracy” require limitations of the contents that the popularly controlled decisions may have? On this question, there is widespread controversy and no definite conclusions to be drawn from the material.

The methods requirement takes the form of a definitional statement; factual disagreements on this point concern institutional devices developed to ensure maximal efficiency of control.

The conditions requirements more often than not take the form of factual statements; disagreements concern empirical relations between economic, social, educational, communicational conditions on the one hand and the efficiency of popular control on the other.

The contents requirements express value statements more than anything else; disagreements concern the purposes that popular control ought to serve, and opinions vary from the acceptance as “democratic” of any decision the people may make—be it even directly suicidal—to the restriction of “democratically” acceptable decision contents to full conformity with an a priori theory of what the real interests and the real goals of the people are.

How do the terms *political democracy* and *social democracy* stand in relation to the distinctions thus made?

Most of the respondents seem to hold that *political democracy* is the more precise term of the two. It is not held to coincide, however, with the “narrow” methods concept outlined in the questionnaire; it is broader because it implies criteria that fall under the conditions requirements. Among such criteria, the material gives prominence to conditions roughly indicated by phrases such as “absence of intimidation,” “freedom of expression,” and “open access to information on public issues.” There seems to be practical agreement in the material that regimes not fulfilling criteria of these kinds should not be called political democracies; the trouble is that there is little agreement on the interpretations of these criteria in concrete contexts.

Social democracy is generally held to be much vaguer in its connotations. Interpretations differ markedly in the material under scrutiny. To some, the term simply signifies an organization of society establishing maximal equality of status in all respects: distribution of power, authority, respect, prestige, economic benefits, legal security, education, and so on. Others do not include equal distribution of power in the connotation of the term, thus contrasting it to political democracy. Still others do not include the economic element, thus distinguishing “social” from “economic” democracy. A considerable number leave out the emphasis on uniform equality and equate “social democracy” with “the general welfare of the

people," "the process of raising the economic and cultural level of the masses," and so on. Some explicitly identify it with government for the people, demophilia, as contrasted with democratia, government by the people.¹⁰⁴ Another potent source of ambiguity is introduced when the term *social democracy* is not only used to define goals to be attained but is focused on sets of means advocated for their attainment; thus, a considerable number of respondents identify the meaning of the term with measures and policies like socialization of the means of production, abolition of private property, and governmental planning and regulation of economic life.¹⁰⁵

All these divergencies in usage result in a confusion of issues and a mingling of problems that make systematic comparison of expressed opinions highly difficult. So complex and varied are the relations of facts at the bottom of ideological controversies that formulations of questions and answers in terms of general catchphrases and stereotypes can only obscure and jumble up the issues. Clarification can be achieved only through a painstaking process of differentiation, specification, and explication.

A number of respondents stress this point in their comments on the two questions raised on the mutual relationship between political democracy and social democracy.¹⁰⁶ Thus, Lewis finds the questions unanswerable because of the ambiguities of the terms to be related; to him, *social democracy* may mean economic equalitarianism or its very opposite, all depending on the general will of the people and the context in which it has to act.¹⁰⁷

Some respondents have tried to formulate in their own manner what they consider the fundamental problems involved in the vague opposition of "political" and "social" democracy. In this way they have made a more definite contribution to clarification than those who have contented themselves with setting forth their responses without making explicit which interpretation of the questions they are answering. The UNESCO questions were deliberately stated too vaguely and generally to admit of straight answers: the experts consulted were thereby urged to reformulate the problems in their own ways and thus further the clarification process by attacking them from different angles.¹⁰⁸

Explicit reformulations and implicit interpretations have largely revolved around two fundamental questions: (1) the relations of conditions to

methods of decision making, and (2) the relations of methods to contents of decision making.

In a first approximation, there may be said to be widespread though implicit agreement that these problems may be expressed in formulations more or less equipollent with the following: (1) Under what conditions—social, economic, educational, communicational—will methods of popular control of governmental decision making function efficiently? (2) What methods of control of decision making are most likely to ensure the formation of governmental decision contents aiming at bringing about optimal conditions of demand satisfaction for the people?

Answers to questions along these lines diverge partly because each element in their formulation is differently interpreted in different contexts, partly because different theories are held about the actual empirical relationships between the sets of facts denoted, and partly because different value orientations lead respondents to focus on different aspects of the problem clusters outlined.

Question 1 leads most of the respondents to tackle the problem of the economic foundations of democracy. Can the masses of the people express their will adequately in a social organization based on private ownership of the means of production? Can the masses control governmental decision making if all economic power is vested in the higher bureaucracy of the state? Can the people get to know what its interests are and find adequate and efficient expression for them if all instruments of large-scale opinion formation are controlled by groups bent on keeping the masses in a state of submissive obedience?

Major disagreements are evidenced in answers to questions in this category. The discords are partly focused on the definition of what constitutes “adequate control of decision making,” partly on hypotheses on the conditions of independent opinion formation, partly on the criteria to be postulated for the determination of the “real” interests of the people.

Question 2 has absorbed the attention of even more contributors: it raises one of the pivotal problems in current ideological controversies. In more concrete terms it might be formulated as follows: if the entire adult population is given access to control of public decision making in a society characterized by trenchant inequalities in social and economic status, will the contents of the thus controlled decisions be such that they will make

for a leveling out of inequalities and a general increase in the welfare of the people?

It is very difficult to give brief formulations of this problem without running the risk of accusations of ideological bias. It is even more difficult to report objectively on trends in the responses registered. Tentatively, two trends may be distinguished and roughly formulated in this way:

2.1. Popular control of decision making must be expected to lead to increased and generalized welfare because the people can be assumed to perform the control in the interest of the satisfaction of its own demands; any social reorganization for the improvement of general welfare must meet the test of actual preferences in the people and cannot be based on theoretical and a priori conceptions of what is "really" the optimal state of society and the "only" means to establish it.

2.2. Popular control of decision making does not necessarily lead to a state of general welfare because in a society characterized by economic inequalities the opinions and attitudes of the people are not developed to the point of conformity with its interests: a social reorganization is necessary to create the conditions that alone can make for efficient and adequate popular control of decision making.

In their extremes, these two trends may be exemplified for the first line of argumentation by Field's contribution, and for the second by Lefebvre's.

Field concludes his analysis of the problem by announcing as his choice for a platform slogan for democracy not the hackneyed Lincolnian formula but the words of William Jennings Bryan: "The people have a right to make their own mistakes."¹⁰⁹

Lefebvre develops the distinction between form and content to the point where he opposes to the Marxist definition of democracy by *the interests of the people*, a *formal* democracy "based on the body of opinions, more or less transient, more or less variable, and more or less well founded of the individuals constituting the majority."¹¹⁰

"It is not impossible that, at a particular time, one man, standing alone or almost alone, may be the true representative of a people or of all the peoples, and the whole of mankind. . . . May it not seem that Lenin, in

1914 . . . , stood for the true understanding of the historical situation, in spite of his isolation? That he thus became an active factor in that situation, grasped the content, the real significance and the underlying trend of history and was working *for* the people.”¹¹¹

This deep-rooted opposition in outlook and value orientation has been given thorough attention by a number of contributors. Eric Weil builds up his entire essay around this dichotomy.¹¹² Bettelheim,¹¹³ Ducasse,¹¹⁴ Lindsay,¹¹⁵ McKeon,¹¹⁶ Patri,¹¹⁷ Plamenatz,¹¹⁸ Pool,¹¹⁹ and Eisenmann all contribute significantly to its clarification.

The opposition owes partly to differences in *expectations* of results from the institution of democratic methods of decision making. General hypotheses about the relationships—causal or otherwise—between methods and decision contents can scarcely be formulated or made testable: there are an infinity of factors to take into account, not the least of which are such relative intangibles as personality traits and general characteristics of behavior and attitudes in the peoples in question. In addition, the opposition must be seen in the light of conflicting value orientations resulting, on the one hand, from actual satisfaction with and support of the social order in question and, on the other, from actual impatience and discontent with the same social order. Supporters of the existing order may be presumed to be interested in preserving actual methods of decision making in the hope that popular control will not lead to radical social changes, at least not in aspects important to them. Opponents of the existing order will tend to be impatient with the working of the actual method of decision making and attribute its failure to the immaturity of public opinion preserved through centralized control of opinion-molding institutions. It is important to emphasize, however, that both sides in the opposition profess unswerving allegiance to democracy as a method of popular control of and participation in governmental decision making; the central difference lies in their opposed evaluations of the actual conditions under which the method is functioning. The analysis of question 2 thus leads back to renewed scrutiny of question 1: under what conditions will methods of popular control work efficiently?

This leads us straight on to an inquiry into the crucial differences between the ideological systems that stand in most direct opposition in current controversies: the Eastern and the Western.

The Crucial Differences

The UNESCO questionnaire was deliberately focused on the ideological opposition that makes up the greatest potential threat to world understanding and enduring peace: the opposition between the social and political views taken in western Europe and the western hemisphere, and the social and political views taken in eastern Europe, the Soviet Union, and communist China. There is no way of making this opposition simple and clear-cut; the actual variety of opinions and outlooks is too great in both camps. There tends, however, to be general agreement that the power conflict between the two groups of people stands in direct, if not always clear, correlation to a more deeply rooted opposition of ideological principles, theories, and value systems. A main purpose of the UNESCO inquiry was to encourage ideological experts to formulate their views of this opposition and assess the possibilities of its reconciliation and peaceful solution.

Formulations of the opposition show striking variations. On the level of mutual vilification, both camps have formulated their difference as one between "real" democracy and "mock democratic forms" masking the ruthless dictatorship of one group over the rest of the people. On a more reflective level, the opposition has variously been characterized as one between a "libertarian" and an "authoritarian" democracy, between Girondism and Jacobinism, bourgeois liberty and socialist equality, capitalist exploitation and working-class liberation, individualism and collectivism, an open society and a closed society, and so on. The amassing of slogans and stereotypes of these kinds has not contributed much to clarification. Fortunately, the material collected occasionally penetrates deeper into the analysis of the problems raised by the existence of this opposition.

To connect the discussion with the distinctions introduced in the analysis of meanings of democracy, the questionnaire took off from the "majority rule"—"majority interest" formulation coined by Bertrand Russell.¹²⁰ This seems to have been a fortunate choice because reactions proved very varied and threw light on the problem from many different angles.

Most of the respondents seem to accept the Russell formulation as a first approximation to a description of the central difference; among these respondents are undoubtedly ideologists from both camps. Evidently, the formulation is not taken as offering more than a rough indication of where

to look for the decisive difference; a one-sentence dictum could scarcely achieve much more. Those, therefore, who set forth accusations of oversimplification and distortion of issues seem to have overlooked the limited pretensions of the formulation.

However, all the attempts at closer scrutiny that are found in our material reveal the need for further differentiation and greater preciseness in the formulation of the opposition of ideologies. It may be that the Western ideology can be said to emphasize the “by the people” aspect, but it is important to specify in what sense this is true, because there seem to be other senses that make Eastern ideologists just as firmly adherents of “government by the people.” Inversely, it may be plausible to hold that Eastern ideology gives predominant emphasis to the *for* element, but it is highly important to distinguish the sense in which this is true from the sense in which Western ideologists may be said to advocate “government for the people.”

The need for more elaborate distinctions is particularly urged by G. A. Borgese,¹²¹ McKeon,¹²² Ossowski,¹²³ Pool,¹²⁴ Schlesinger,¹²⁵ and Sweezy.¹²⁶

Sweezy takes sharp issue with the identification of Western democracy with “majority rule.” Quite to the contrary, it seems to him to mean “the inviolability of the rights and privileges of minorities,” in concreto, the privileges of the propertied classes. Ducasse,¹²⁷ Field,¹²⁸ and Ewing take him strongly to task for this statement. It seems that he would have made a stronger case for himself if, instead of imputing to his opponents meanings they would scarcely acknowledge as theirs, he had elaborated the hypothesis that under Western conditions of economic equality the majority of the people are unable to make their demands count despite the existence of universal suffrage rights and normal election procedures.

On the other hand, Sweezy accepts the Russellian definition of Russian democracy as rule in the interests of the people and amplifies it by stating as the essence of the Soviet conception “the elevation of the economic and cultural level of the masses”; but he adds, very significantly: “and their active involvement in public affairs.” In this way, the Soviet conception is made to appear to give emphasis to the “by the people” element, too. Bettelheim,¹²⁹ Lefebvre,¹³⁰ and Ladislaus Rieger¹³¹ all concur in this analysis. Schlesinger is particularly concerned with developing the point. In his view, the Bertrand Russell formulation of the East-West opposition over

democracy is dangerously misleading.¹³² In a lengthy and well-documented analysis of Soviet ideological texts, he develops the view that mass participation in the formation and execution of public decision making and not just the raising of the standard of living of the masses is the essence of Soviet democracy. He expressly rejects the assumption that it is "government for the people" in the sense of concentration on mass consumption; improvement in economic conditions is not deemed an end in itself, but an indispensable means of bringing about the "active involvement" of the masses in public affairs.¹³³

Inversely, a number of respondents resent the implication that Western democracy is only by the people, not for the people; in their view, the democracies are much more for the people since the general welfare developed has come about through deliberate action by the people. The by-for dichotomy is rejected as unrealistic and invalid by several contributors. Thus, Borgese says: "[I]t is impossible to conceive 'a rule of the majority' in which that rule is or may be deliberately or consciously at variance with the 'interests of the majority.' Such a democracy should be defined as the government of the people by the people against the people. . . . If 'democracies' of this kind were extant, there would be a point in Gromyko's definition of his own 'people's democracy.' Our purpose, he said, is the well-being of the people, 'whether they like it or not.'"¹³⁴

Argumentation along these lines raises anew the two problems outlined in a previous section: (1) Under what conditions can the people be expected to act politically in open consciousness of its "real interests"? (2) Can the "real interests" of the people be determined theoretically prior to observations of its actual preferences and overt choices?

Scrutinizing the philosophical implications of these problems, McKeon arrives at the conclusion that the West-East opposition cannot possibly be formulated in terms of a by-for dichotomy. "The broader opposition is between the use of factions and classes as a safeguard of the common good, and the appeal to wisdom or knowledge for the discrimination of the true good from the common good. . . . The one conception of democracy . . . would provide for social, economic, and political decisions, and even for the use of science in arriving at these decisions, within a frame that makes possible the resolution of differences, according to the preference of the majority, on the assumption that no one has infallible

scientific knowledge in any sphere and that the progress of science no less than the equitable resolution of differences depends on the toleration of diversity. The other would provide for social, economic, and political decisions through the application of the principles of dialectical materialism in resolution of problems in these spheres by the party of the proletariat, on the assumption that the method of dialectical materialism is the true scientific method and that not even all workers (since they have been demoralized by capitalism), much less the capitalists and those who incline toward capitalism, can contribute to the decision."¹³⁵

To McKeon, the focus of controversy is thus on the cognitive status of political propositions: Are they invariably fallible expressions of the conflicting or converging interests of the groups that make up the people, or can they be made into infallible scientific statements of measures and policy for the attainment of a state of society in true harmony with historical laws of development? Can, in general, political problems be solved by a science of society capable of establishing true statements that everybody will have to accept?

The discussion is thus transferred from the realm of sociopolitical relations dealt with in part B of the questionnaire to the problems taken up in part C: can scientific knowledge of social processes be developed to the point where an end of opposition to and criticism of the conclusions to which it leads can be justified?

This problem is discussed in an illuminating way in the comments made by Ducasse¹³⁶ and Field¹³⁷ on the position taken by Sweezy.¹³⁸ the discussion of democracy is clearly seen to open a highway toward the clarification of basic issues in contemporary epistemology and methodology.

Marshall and Pool¹³⁹ develop views on the East-West opposition closely related to those taken by McKeon, Ducasse, and Field; but, instead of the philosophical, they concentrate on the psychological aspects of the opposition. To them, the opposition is one between appeals to different personality types and ideals of interpersonal relationships; on the one hand, the emphasis is on the development of self-reliant, independent personalities free to challenge and criticize the authority and the theories of those in power, be they capitalists or bureaucrats; on the other, the emphasis is on the molding of submissive and obedient personalities lastingly conditioned to unquestioning reverence for authority and the ideologies of

the power holders. On the institutional level, this opposition translates into one between, on the one hand, devices for efficient expression of a plurality of opinions and the formation of a plurality of parties and pressure groups and, on the other hand, devices for the *Gleichschaltung* of opinions, the elimination of nonconformity, and the establishment of single-party government.

A survey of the opinions registered in the material on the question of the crucial differences between the Western and the Eastern ideological outlooks reveals in both camps a marked tendency to mold analytical distinctions onto the value orientations already taken for granted. Formulations of the crux of the opposition vary with ideological affiliations: the value attachments of the analysts determine their perspectives to a degree that makes agreement on the nature of the problems at issue virtually unattainable. Of particular interest is the widespread tendency to formulate oppositions in terms that set off the lofty aspirations of the one camp against the meager achievements of the other. A basic prerequisite for clarification would seem to be to reach an agreement either to stick to aspirations on both sides or to concern oneself solely with the dismal realities of actual achievement. In the former case thoroughgoing comparative studies in ideological argumentation might clear up what is as yet a virgin field for dispassionate research. In the latter case empirical investigations of social and political structures in their relation to actual attitudes and wants are urgently called for to set off in a truer light the teeming multitude of ideologically tilted statements that thrive on our general ignorance of the facts involved.

Opinion: Influence Versus Pressure

A problem constantly recurring in ideological analyses—outside as well as inside the UNESCO material—is this: how are the “real interests” of an individual or of the people to be determined?¹⁴⁰

A number of respondents, particularly Ducasse,¹⁴¹ Plamenatz,¹⁴² Brown, and Ranulf, agree in considering this the most fundamental of the issues taken up in the inquiry, but almost no one has ventured farther into this highly controversial and extremely difficult matter.

The main difficulty lies in the establishment of intersubjective agree-

ment on criteria and conditions of “realness”: it seems practically hopeless to disentangle what an individual is wanted to want from what he may be predicted to want under given circumstances.

Ducasse suggests this general formulation of criteria: “The real interests of the individual are those he actually prefers when he (a) knows what the possible alternatives are among which a choice is possible, and (b) knows both the hidden price and the hidden values, as well as the surface price and values.”¹⁴³

The crucial factor in this as well as in a number of less articulate formulations is the amount and reliability of information conditioning the preference. The analysis of the function of this factor leads to a general discussion of the conditions of opinion formation in societies that claim to be democratically governed. In the UNESCO questionnaire the question was given the form “In general, how would you trace a line between ‘democratically justifiable’ and ‘democratically unjustifiable’ processes of opinion-influencing?”¹⁴⁴

Responses to this question evidence a surprising degree of agreement. It is true that almost none of the respondents try to trace any definite line of demarcation of the kind asked for. This they consider futile and close to impossible in view of the tremendous differences in concrete situations. There is a large consensus, however, on the general standards to which opinion-influencing should ideally conform in a democratic society: these may not be explicitly or fully stated, but they may safely be said to be implied by the overwhelming majority of statements made on the subject.

It must be emphasized that the general consensus thus registered holds only on the level of ideals. There is extreme disagreement on the conditions making for optimal fulfillment of the ideals, whether in a capitalist, a social democratic, or a communist organization of society.

The ideals of democratic opinion-influencing implicitly agreed on by the respondents may very tentatively be formulated and classified as follows:

1. *Full information.* If and when a public is invited to express its opinion on an issue, the whole of the public should be given the means to acquaint itself with all arguments it would possibly consider relevant to the issue. Descriptions of what is at stake with regard to the issue should be as impartial as is feasible. If a small group within

the people has informational privileges, for example, by its position in the governmental bureaucracy or in the direction of a large financial or industrial concern, the public should be granted access to any part of the informational material of the group that would possibly be considered relevant to the issue.

Only if these conditions are fulfilled are individuals and groups justified in making propaganda for a particular solution to the problems involved. As long as the public is deprived of tools with which to resist opinion-influencing, any invitation to take an independent part in decision making is nothing but hypocrisy.

2. *Education and leisure to digest information.* If a group cannot partake in decision making because it lacks the general education and leisure that are at the disposal of other groups, every available means should be used to remove the disproportion. The more decisions touch the specific interests of the handicapped group, the more urgent is the elimination of these inequalities.
3. *Honest presentation of issues.* Given the inescapable fact that a public cannot effectively partake in all decisions affecting its welfare, the influence expert is forced to make a choice not only of issues for presentation, but also of aspects of the frequently complex problems involved. The temptation is always great to interpret expressions of public opinion and election results to imply positive or negative stands on questions never envisaged by the public. By refined and subtle as well as by crude and obvious bias in the presentation of public problems, the opinion molders can easily use this process of interpretation and elaboration to falsify the general picture of public opinion to suit their own interests. By clever selection of issues for presentation and by focusing public attention on those thus selected, the opinion leaders can elicit responses easily fitting their preconceived patterns and avoid responses that might be embarrassing or clearly opposed to their interests.

On the basis of these considerations, a third ideal may be formulated: if and when complex problems are brought before the public by groups with information privileges controlling means of mass communication, the selection of issues for public discussion and decision making should be such that the public is granted an

adequate chance to influence decisions on issues vital to its own interests and to influence them in directions that may go counter to those advocated by the groups enjoying influence privileges.

4. *Absence of intimidation.* Voting and opinion declarations of a similar character should not be influenced by threats of reprisals or promises of rewards. No pressure other than that of relevant arguments should be deliberately used in attempts to influence opinion. In particular, unpopular minority opinions should be protected against groups exploiting the prestige of popular majority status as a means to counteract minority influence.

These and other closely related ideals can, of course, be formulated in very different ways. The ones adopted express only a few of the many possibilities.

The advocacy of these ideals of opinion-influencing does not necessarily imply more than that their realization is viewed as something desirable. Consequently, there is no need to be committed to viewing their violation as more undesirable than the violation of any other ideal. Ideological controversy creeps in as soon as, in concrete situations, attempts are made to assign a "proper place" to ideals in a *hierarchy* of interests and norms.

As soon as the discussion shifts from the proclamation of ideals to the concrete confrontation of ideals clashing with ideals and of ideals clashing with what are considered "necessities," the analysis of agreements and disagreements becomes vastly more complicated. It is not at all surprising that so many of the respondents have found it impossible to trace any sharp line between "justifiable" and "unjustifiable" procedures of opinion-influencing.

Tolerance and Treason

What Should Be Repressed?

Answers to the third part of the UNESCO questionnaire include judgments on things, x , that should be tolerated or not tolerated, or that can or cannot be tolerated. The x 's are labeled by not too clear designations such as "antidemocratic propaganda," "attacks on democratic institutions," "pro-

paganda to change the form of government," "groups promoting a regime that would destroy the advantages of democratic procedure," "treason," "proposed changes through violence," "dangerous propaganda," "antidemocratic propaganda presenting a clear and present danger to the constitution," "people who do not support the existing social order," "opinions that make for insurrection," and "secret organization with the goal to change the form of government."

To compare the opinions of two ideologists one of whom tells us that we should not tolerate x , whereas the other tells us that we should tolerate x , we shall have to make sure that they are speaking of the same x 's, the same things—a task that often proves quite difficult. There is a tendency to class one ideologist as more tolerant than another if he proclaims tolerance and denounces intolerance in a louder, more emphatic or pointed way than the other. Close analysis may reveal, however, that the things x_1 , which the seemingly very tolerant person tolerates, represent a much narrower class of things than the class of things x_2 , which the seemingly less tolerant person is willing to let develop undisturbed. Or analysis may reveal that the designations used to characterize the x 's are too crude to warrant any conclusion as to what the ideologists in question wish to tolerate and what they do not. Here, as in many other cases, we shall have to analyze the actions of groups in order to be able to judge what they mean by their words. It is important to note, however, that inferences from nonverbal behavior are open to serious pitfalls even if made by neutral observers.

To obtain a survey of some important stands taken in the tolerance discussion, we shall work with the following classification of things that should or should not be tolerated:

x_1 : opinions, advocated or not advocated in agitation, that, if held by sufficiently many, are apt to justify acts undermining the democratic form of government, or acts that would make it less democratic; the acts in question may be lawful within a democracy

x_2 : opinions advocated in agitation that, if held by sufficiently many, are apt, etc.; the acts in question may be use of force, insurrection, high treason

x_3 : agitation explicitly justifying acts of incitement to acts undermining the democratic form of government

x_4 : incitements, direct planning, and organization aiming at forceful overthrow of the democratic form of government

These very roughly delimited classes of things are sufficiently different to make it important to know which, if any, of them a given ideologist proposes for repression.

To avoid introducing tremendous complications, we have not differentiated between different concepts of “democratic form of government” and “less democratic.” This seemingly uncritical attitude is based on the following opinion: however great the differences are between concepts of democracy, there is practically full agreement that the word should stand for something very valuable, something that is worth establishing or maintaining. Whatever their particular definitions of democracy may be, the ideologists’ answers therefore reveal how they conceive of relations between things very valuable and policies of repression.

There are other distinctions, however, that are just as important as the distinction between classes of things tolerated. Suppose one respondent advocates repression of a relatively wide class of phenomena but adds that he takes as a premise that the times are troubled, that there are enemies of democracy who, if given the opportunity, could profit by the mere existence of opinions of the kind x_1 . Thus, the seemingly intolerant ideologist may limit the intended field of application of his principles to a very narrow class of historical situations, whereas a seemingly tolerant ideologist preaching suppression only of things of class x_3 may choose a very wide field of application for measures of repression. Close analysis may reveal that he means that in times of slight troubles of a rather common type, a much wider class of opinions and acts should be repressed. Thus, to understand the import of views proclaimed, it is necessary to try to find out *under which conditions*, historical, social, economic, and so on, the recommendations are expected to apply. If we call these circumstances the y -conditions, we could specify different y -classes such as:

y_1 : *all* conditions (i.e., suppression under any conceivable circumstance)

y_2 : times of trouble, of economic crises, of internal stress

y_3 : times of civil war or of impending or actual international war

Third, two ideologists both proclaiming that something ought to or must be suppressed may possibly mean rather different things by "suppression." If, for example, the one by suppression thinks only of legal prosecution by the authorities of the country, whereas the other by suppression means any means whatsoever of putting an end to something, the seemingly tolerant ideologist saying that antidemocratic propaganda should not be suppressed may in practice be less tolerant than one in favor of suppression: the one may advocate very effective measures of social discrimination, economic boycott, and so on, whereas the other may reject these measures but recommend suppression in the sense of legal prosecution with lenient rules. Mostly, but not invariably, the "suppression" and "nontolerance" spoken of in the answers relate to the question of interference by state authorities. Thus, we have a third variable to take care of when interpreting the ideologies of toleration and suppression; let us call it the *z*-processes: those constituting the *kind* of suppression or noninterference contemplated.

Although very few of the respondents have gone into detailed analysis of the difficulties involved in delimiting areas of tolerance from areas of suppression, most of them emphasize the practical impossibility of formulating universally valid and applicable rules in the field.

These difficulties are reflected in the confusing variety of opinions registered in the material. Any attempt to classify opinions on the tolerance problem runs the risk of distorting the significance of the statements made. Almost all formulations of scope and limits of toleration are studded with vague value expressions that make it a venturesome task to locate them even approximately along the *x*-, *y*-, and *z*-axes of reference suggested.

The majority of the respondents focus their discussion on the tolerance requirements implicit in their conception of democracy: their main concern is with the problem of whether allegiance to "democracy" implies the duty of tolerating or repressing opinions directly or indirectly aimed at overthrowing and destroying the institutions and structures they identify with democracy.

Pool,¹⁴⁵ Ross,¹⁴⁶ and Ranulf advocate the toleration of such opinions, at least insofar as they may be classed under x_1 , x_2 , and x_3 , but probably not under x_4 .

Ross distinguishes, however, between opinions and the *means* used to propagate them; just as he does not accept the toleration of physical con-

straint and violence as means of propagating an opinion, he will not tolerate the use of deceitful agitation and fraudulent distortion as means to gain adherence for it.

A number of other respondents seem willing to defend and advocate the toleration at least of opinions of classes x_1 and x_2 : thus Edgar F. Carritt, Ewing, Lovejoy, and others. It is very difficult, however, to map out exactly how opinions are divided. The distinctions between opinions according to the directness of their relations to overt acts of violent subversion are at best very fuzzy. Some respondents, particularly McKeon,¹⁴⁷ Brown, and Hans Kohn, seem to find a reliable guide in the famous “clear and present danger” rule coined by Justice Holmes. It seems doubtful, however, whether a rule of this kind can fruitfully be applied under circumstances of such ideological complexity as those prevailing in our day.

A number of respondents discuss the limits of toleration directly in terms of their interpretations of the requirements of democracy.

Sweezy¹⁴⁸ and Hollis agree that any curtailment in the freedom of opinions is ipso facto a move in the direction of “less democracy”: this does not exclude, however, that in concrete situations such moves may be deemed perfectly justifiable.

Others emphasize the right and duty of their “democracy” to defend and protect itself from being undermined by opinions that might bring about its destruction. Democracy does not imply an obligation to commit suicide, as Horvath puts it.¹⁴⁹

Some stress the necessity of repressing opinions directed against democracy as a *method* of decision making. Others go farther and require that opinions going counter to and endangering “democratic” decision *contents* be repressed: thus, Bettelheim,¹⁵⁰ Lefebvre,¹⁵¹ and Rieger¹⁵² all seem to think that any democracy, whether bourgeois or communist, will only tolerate opinions favoring the social order on which it is based. They even go farther to state that repression of opinions is compatible with democracy if it is directed against groups bent on reversing the trend toward greater and broader democracy.

A similar view is taken by Sweezy, but not on any basis of deduction from a definition of democracy: in his view, suppression of opinions is justified if designed to further the progress toward greater democracy, but not justifiable if it paves the way for further infringements of democracy.

A slightly different trend of argumentation is manifest in the Jørgensen contribution: antidemocratic propaganda should not be permitted as long as differences in social, economic, and educational status make parts of the population unable to resist such propaganda.¹⁵³

The less ideologists find themselves content with proclamations in terms of vague value judgments, the more they are forced to penetrate into the realm of concrete complexities of cases and situations. If current ideological doctrines were analyzed from a casuistic angle instead of an idealistic one, their interrelations would be found to be marked by incomparability rather than by incompatibility. Each ideological system bears the marks of its formation under the impact of states of affairs never seriously envisaged in rival systems. Ideologies cannot be understood and clarified unless they are seen against the particular historical setting in which they have developed, and related to the particular state of affairs faced by those who have vindicated them as well as those who have accepted them and believed in them.

It is not the aim of the present analysis to take up causal points, but I hope I am excused for suggesting that the ideological controversies owe in part to the general neglect of explicit statements of past and present conditions limiting the intended validity of ought-, should-, and must-sentences. That this neglect has its distinct advantage in consolidating in-groups and justifying hostility toward outgroups may to some extent explain why it has not been more seriously combated.

One-Party Systems

On the level of surface expressions, the respondents may be divided into four groups: (1) those who find one-party systems incompatible with any democracy; (2) those who find one-party systems compatible under some conditions and for some of the established usages of the term *democracy*; (3) those who find one-party systems compatible with democracy, without any reservations; (4) those who consider the party question irrelevant to the question of whether a regime is or is not democratic.

A definite majority of the respondents take the position that one-party systems are incompatible with democracy: Lewis,¹⁵⁴ Patri,¹⁵⁵ Plamenatz,¹⁵⁶ Wright,¹⁵⁷ Eisenmann, Hagopian, Wilson Martins, Nomad, et al.

Horvath,¹⁵⁸ Jørgensen,¹⁵⁹ and Ricardo R. Pascual take the view that, ideally, democracy does not require the institution of a party or parties; the only compatible system is a no-party system.

A few contributors, particularly McKeon,¹⁶⁰ Pool,¹⁶¹ Farber, and H. J. Simons, find that one-party systems may be compatible with democracy in societies characterized by conditions like homogeneity of attitudes and valuations, absence of public issues, identity of interests, etc., but they all emphasize that these conditions are so rarely found and so unlikely to be realized that one-party systems can be considered incompatible with democracy in all major societies of the present age. Inversely, group 1 may be inferred to agree that under most of the extreme and unlikely conditions listed by group 2, one-party systems would be compatible with democracy. Thus, the surface disagreement may be discounted as a verbal one.

Another potent source of verbal disagreement lies in the fact that few of the respondents have made explicitly clear what usage of *democracy* they are referring to in their judgments of compatibility or noncompatibility. Group 3 and to a large extent also group 2 seem to be using *democracy* in a broader sense, which respondents in group 1 would quite certainly not recognize as theirs.

Some respondents introduce distinctions according to usages: thus, Logemann,¹⁶² Perelman,¹⁶³ Bochenski, and others emphasize that, although one-party systems may be incompatible with democracy in the Western sense, there are certainly other plausible senses in which even proletarian dictatorship and Fascist totalitarianism will be found compatible with democracy. It is obvious that if broad usages of these kinds are adopted, answers to the one-party question cannot very well be anything but positive.

The members of group 3 manifest close similarities in their arguments for compatibility: they all stress the uselessness of pluralities of parties if there are no essential differences of opinion among those competent to judge and if the doctrines of the one party in power have the status of science and not mere opinion. If such conditions hold, it is argued, deviations are sure symptoms of incompetence or of unsocial, essentially criminal, behavior.

Thus, Bettelheim,¹⁶⁴ Lefebvre,¹⁶⁵ and Rieger¹⁶⁶ all assert that in socialist society—the only society in which these conditions are or will be

fulfilled—pluralities of parties have no *raison d'être*. Less categorical positions within the same group are argued by Horvath,¹⁶⁷ Jørgensen,¹⁶⁸ and Sweezy.¹⁶⁹

What is the nature of the disagreement between group 3 and the other groups? It is not necessarily based on terminological deviations. Group 3 may well adopt the same usage of *democracy* as, say, group 1 and yet be able to argue its case. The difference is one of perspective and outlook: conditions of society and developments in social knowledge that the one group considers close to realization are by the other groups held to be very far from realized or even impossible of realization. The real issue is not whether one-party systems are compatible or incompatible with democracy, but whether the conditions of unanimity of opinion, community of interests, and absence of issues that alone are agreed to justify one-party systems are realized or likely to be realized in any of the societies existing in our age. On this issue, opinions clash in a real way: they mirror the general opposition evidenced in ideological controversies over the status and potentialities of social science and over the scope of toleration of dissenting opinions and critical attitudes.

Scepticism and Democracy

The problems of toleration and repression lead directly to fundamental philosophical questions of the validity of ideologically opposed opinions and the possibility of establishing a science of society capable of commanding universal consensus for its conclusions.

In the UNESCO questionnaire the problem was formulated in terms of the relations between “scepticism” and “democracy.”

Philosophical dichotomies like scepticism versus dogmatism, relativism versus absolutism, fallibilism versus infallibilism, empiricism versus rationalism have come to play pivotal parts in twentieth-century ideological controversies. In the 1920s and 1930s, a significant trend in political argumentation focused on epistemological and axiological scepticism as a basis for theoretical defense of a formal methods conception of democracy as against the contents conception advocated on the left as well as on the right on the basis of philosophical absolutism and dogmatic rationalism.¹⁷⁰ In later years ideological controversies have even more pointedly

been concentrated on basic philosophical issues; the debate has been pushed far beyond questions of political and economic instrumentalities toward ultimate problems of cognition, valuation, and normation.

In the questionnaire a suggestive catchphrase coined by the British political scientist D. W. Brogan was chosen as a point of departure for the discussion: "Scepticism is part of our faith."¹⁷¹

No straight answers to the question could be expected. It was hoped, however, that respondents might feel provoked to answer in terms of kinds of scepticism and kinds of subject matters to be sceptical about. As a slogan in ideological debates "scepticism" may not indicate more than an attitude of doubt toward things on which the user wants to focus attention.

As might have been anticipated, the Brogan formula was interpreted in strikingly different directions. There is, accordingly, little sense in classifying responses according to surface agreements or disagreements.

It is highly important, however, to note the near-automatic rejection of the Brogan formula by all those who advocate the justification of one-party systems: to them, scepticism seems to be a term of strictly dyslogistic connotation only to be applied to wavering and uncertain opponents. Taking for granted that a reliable science of society has been developed and that competent and honest people necessarily agree on basic issues, they cannot but find the Brogan formula a highly misleading expression of "democratic" ideology, however the formula might be interpreted.

Jørgensen¹⁷² interprets the question to ask if the view that human beings are incapable of deciding whether or not divergent political proposals and measures are equally good can be used as an argument for the establishment of democracy in the sense of majority rule. He rejects the view both as in itself tenable and as a valid argument for political democracy. In this conclusion, we may infer, probably all the respondents agree; Jørgensen is the only one, however, who has gone into detailed analysis of the problems involved.

Wright¹⁷³ emphasizes in a similar way that if scepticism is taken to mean that "all views are equally valid or invalid," it does not have any affinity to requirements of democracy. There is nothing to indicate that any respondent would disagree with him on that point.

Sweezy rejects the Brogan formula on the basis of a similar interpretation of scepticism: he argues that the existence of a science of society re-

futes the claim that “all opinions are equally valid” and concludes that there is no longer any justification for raising scepticism to the level of a principle of democratic ideology and for denying “that one political creed may be more compatible with democracy than others.”¹⁷⁴

In their criticism of the position taken by Sweezy, Ducasse,¹⁷⁵ Field,¹⁷⁶ and Pool¹⁷⁷ do not deny that some political opinions can reasonably claim a higher degree of validity than others, but they nevertheless defend scepticism as an important democratic principle expressing the urgency of constant alertness and critical-mindedness, and the conviction that only the open toleration of widely dissenting opinions can provide a safeguard against the perpetuation of errors backed by power and authority.

Lovejoy introduces a set of very important distinctions into the debate on this issue: “Democracy does not imply the assumption that no political principle or assumption can be known to be true. It does, however, imply four assumptions: (a) that any individual’s judgment on a political question may possibly be erroneous; (b) that no individual, as an individual, has a moral right to coerce other sane and adult individuals; (c) that—since, in the political state, it is necessary that on some matters joint and collective action be taken, and also that individuals be protected against coercion by other individuals, through the exercise of coercive power by the state—it is essential that some method be found of peaceably determining what collective action shall be taken and how far and in what ways the coercive power of the state shall be exercised; and (d) that the best and most effective means of settling peaceably such political questions, i.e., questions of state actions, is to permit all citizens of the state to participate in the settlement of them and to accept as the final settlement the decision of the majority. On these propositions democracy does not imply ‘scepticism’: it implies that the propositions are true. It does not, however, imply that the judgment of the majority is inerrant; and it therefore allows freedom to minorities to agitate and vote for the reversal of previous majority decisions.” (personal communication)

It may be inferred that most of those who, like Bober,¹⁷⁸ John Bowle, Brown, Smith, and ten Hoor, endorse the Brogan dictum without reservations also agree to the points made by Lovejoy; the scepticism implied by democracy does not extend to what are considered basic principles of its maintenance and growth. What is basic is, of course, highly controversial and reflects the divergencies in conceptions of democracy; this, however, is

only another way of saying that with the majority of ideologists, the principles lie well beyond the reach of any possible scepticism.

Value Foundations of the Conflict

In the last part of the UNESCO questionnaire, scholars and experts were invited to develop their views of the general philosophical foundations of the conflicts and controversies under scrutiny. A set of very vague and abstract questions and suggestions was given to stimulate reflective commentaries in the direction of formulations of the general nature of ideological disagreements and assessments of the conditions of their possible reconciliation.

Classification of opinions registered in this part of the material is practically hopeless and theoretically close to futile. The questions set forth gave rise to responses in highly different directions, and answers are only rarely comparable because the respondents have focused on different issues and interpretations.

A number of respondents take up for scrutiny the question of whether current ideological disagreements are fundamentally terminological, descriptive, or normative in character.¹⁷⁹

Responses to this question largely reflect attitudes to possibilities and procedures of settlement and reconciliation: should attention and efforts be primarily concentrated on semantic clarification, empirical and theoretical research, or direct action to bring about changes in basic attitudes? No incompatibility is apparent among the views taken by “terminologists,” “descriptivists,” and “normativists”: there is a difference in perspective and approach without direct ideological relevance.

The greatest number of those who discuss this problem tend to stress as the focus of discord a difference in the analysis and theoretical conception of structures and relationships in society: views of this kind are taken by Bettelheim,¹⁸⁰ Bober,¹⁸¹ Horvath,¹⁸² Jørgensen,¹⁸³ McKeon,¹⁸⁴ Ricardo R. Pascual,¹⁸⁵ Sweezy,¹⁸⁶ Eric Weil,¹⁸⁷ and Lien. In principle, a difference of this kind might be expected to diminish with the gradual advance in scientific knowledge of social facts; this is what some of the respondents anticipated, but others point to the force of traditional patterns of thinking and the vested interests of privileged groups as obstacles on the road to settlement. Thus,

Sweezy thinks that what is holding back the development toward general consensus is "that those who have vested interests in the maintenance of capitalism do not want the truth to be taught."¹⁸⁸ Others return similar charges against communists. In the view of Ducasse¹⁸⁹ and Field,¹⁹⁰ there is no cognitive basis for reducing the current opposition to one between scientific truth in the one camp and tradition-molded prejudices and intellectual dishonesty in the other; the differences in analyses and interpretations of social relations reflect differences in value perspectives and political motivations.

Similar conclusions are reached from discussions of the relationships between ultimate political goals and means advocated for their fulfillment.

In the questionnaire, one of Lenin's formulations of the ultimate aim of political activity was given as an example, and opinions on its compatibility with other formulations of ultimate aims were urged.¹⁹¹ None of the contributors takes issue with the ultimate aim formulated by Lenin. There seems to be genuine agreement among all concerned that the ideal end of social development can well be described in terms like those used by Lenin.

As has so often been found in this inquiry, however, general agreement on ideals is unfortunately of little relevance to the clarification of ideological disagreements.

Perelman is particularly emphatic on this point: to him, the controversies are by no means assuaged by "the consoling thought that all political philosophers proclaim the same ultimate goal. . . . The ideological differences relate to real societies and not to utopia. Once conditions allow for the attainment of a utopia, ideological conflicts lose all interest and meaning."¹⁹²

In the same vein ten Hoor comments: "It is possible, of course, to state the aims of government in such general terms that there can be no incompatibility. However, incompatibility becomes a problem when we 'descend' to the level of implications, consequences, conceptions of ends, choice of means, etc. . . . It does no good to devise some generalization which seems to serve no function except to conceal this fact." (personal communication)

It might perhaps be objected that descriptions of ultimate goals need not necessarily be given in excessively general terms. Generality and abstraction are harder to avoid in proclamations on the means chosen to arrive at the ultimate goals.

Respondents generally concede that agreements on ultimate goals are

entirely compatible with robust disagreements on methods to be used in their attainment, on the potentialities of the existing conditions, and on the solution of actual differences of evaluation and judgment.

A number of respondents, however, stress an important qualification: it may well be that ideological controversies are mainly centered on means and conditions, but the possibility is not thereby excluded that the disagreements embrace a decisive *normative* element. Oppositions over the choice of means to a given end do not take place in a vacuum but are conditioned by the existence of a number of diverse intrinsic norms that may preclude the adoption of otherwise effective means. The disagreements are to a large extent concerned with intrinsic norms of this kind; values like the dignity of the human person, intellectual integrity, minority rights, and so forth, are frequently referred to as crucial in these respects. Neither of the parties in the conflict denies any of these values although they may be very differently interpreted in concrete situations: controversies take the form of mutual charges that the values are not respected or lived up to in the opposing camp.

Are the chances of reconciliation better or worse if the conflict turns out to be predominantly descriptive in nature? In the UNESCO questionnaire it was suggested that conflicts turning on ultimate norms might prove irreducible. Several contributors seem to take a similar view and emphasize, with Wright,¹⁹³ that "so long as opinions are regarded as relative and no values in the field are taken as absolute, there is always a possibility of reconciliation or of temporizing."

Others, however, take the contrary view that disagreements on means may well turn out to be equally deep-seated and intractable. Thus, Sweezy states that "people will cling to traditional or accepted patterns of analysis and interpretation just as tenaciously as they will to what are often regarded as more basic value judgments."¹⁹⁴ He even suggests that the very fact that both camps profess their allegiance to the same ultimate goals and values may turn into a source of contention and bitterness; each camp will accuse the other of hypocrisy and deceit.

Among the great variety of reflections made in the material on the general relations of value antagonisms to prospects of diminishing the acuity of the conflict, the following might be singled out as possible points of departure for further mediation:

Conflicting views on ultimates will exclude rational but not other approaches to the peaceful settlement of ideological conflicts. There is, of course, always the possibility that convictions on ultimates may change or simply wither away; this may affect the alignment of agreements and disagreements. The possibility must not be overlooked that ideological clashes are more or less deliberately kept going on semantic confusions and distortions of issues as a means to divert public attention from the nonideological clashes of naked ambitions for economic, strategic, and other kinds of power.

If the ideological conflicts can be traced to different conclusions from analyses of social conditions and to different predictions of how common aims can be achieved, potent rational approaches may be open for the reduction of the more violent consequences of the conflicts. Chances to obtain moral and general ideological sanctions for warlike measures will decrease if the conflict in question is set before the peoples involved as one centered on the choice of effective means for the attainment of compatible if not common goals. The possibility must, however, be taken into account that theories of social conditions and instrumentalities may be stubbornly adhered to in the teeth of otherwise adequate demonstration of their falsity: this emotional and volitional element in social knowledge may prove much harder to cope with and may provide an important obstacle to possible progress toward peaceful settlement of conflicts for a long time to come.

Conclusions

It is perfectly possible to compare ideological doctrines without prejudging the issues by taking a stand for or against some of the doctrines, but this requires a motivation that is rarely found among people who are actively engaged in political struggle.

Even the possibility of comparison has been implicitly denied, particularly by those (Nietzsche, Spengler, Sorokin, et al.) who believe that a human being cannot arrive at conclusions other than those that favor his interests, basic cultural heritage, biological drives, or other noncognitive factors. One of the reasons not to take the statements of these theorists too seriously is that they implicitly assume that they are exceptions to their

own principle. They indulge in vast comparisons and do not seem to doubt the objectivity of their findings.

Stripped of misleading philosophical entanglements, the problem of the objectivity of ideological comparisons seems to boil down to that of getting a sufficient number of researchers of diverse cultural and political backgrounds to work permanently and in a spirit of intellectual integrity on the issues involved.

Today, nationalist trends and political servility are fostered in research centers by their dependence on official bureaucracy or economic power. Social pressure is constantly at work on the researchers to make them produce statements agreeable to the dominant political trends. They are even implicitly expected to adapt themselves to the foreign policy of their nation: in times of shifts of alliances or outbreak of war, sudden shifts in theories are expected. Accounts of the history of allied powers are to be more sympathetic; accounts of hostile powers are to be altered in the opposite direction. There is scarcely a country in which those resisting such “revisions” have not been subjected to crude attempts at *Gleichschaltung*, instead of being encouraged and applauded as valuable organs of equilibrium in the planetary community of men.

Strong currents of international—or supranational—character can reduce the pressure on the researchers and make international loyalties compete with national ones. Such currents cannot prevail, however, without a strengthening of trends toward fair play in the struggle between national or subnational groups who compete for prestige and power. If on the subnational level we have ingrown habits of picturing antagonists in black and ourselves in brilliant white, and of looking at our opinions on controversial issues as absolute certainties while regarding those of our opponents as distorted and biased, we shall have no force to resist prejudged accounts of ideologies. We are easily made victims of “official” versions of the ideological situation.

It should be added that significant progress toward fair presentation of ideological oppositions cannot be expected as long as there is internal strife of such an intensity that a split morality is propagated by all opinion leaders: one when presenting the outgroup’s platform and another reserved for the ingroup.

These are reflections relevant to any conclusions on findings on ideo-

logical differences in our age. The ensuing statements of conclusions must be interpreted against the background of these reflections.

1. The material gathered by UNESCO reveals that even among specialists in ideological research there are great *differences of opinion as regards matters of fact* of unquestioned relevance to the description of ideological antagonisms.

2. Consequently, a large proportion of the statements made in the contributions should be viewed as expressive of *working hypotheses* justifiable on the basis of present-day efforts in ideology research, but subject to continuous corrections in the future.

3. It is beyond the powers of present-day research to determine in any exact way the lines of agreement and disagreement between ideological doctrines. If sufficient knowledge were stored in individual minds, it could not easily be conveyed to others. Present-day language habits are not adapted to the immense task of exact comparison of beliefs of groups and nations engaged in struggles for material and spiritual dominance.

4. Attempts at such a comparison encounter the difficulty that the language habits are adapted to agitation and preaching in the field of ideology, not to fair presentation. Basic terms in the vocabulary of ideologies are emotionally loaded slogans, and to make them resistant to analysis is a virtue in the eyes of the indoctrinated.

5. The function of ideologies to stabilize motives of joint action and encourage the fighting spirit of their adherents, makes it of little concern to ideologists to formulate carefully the particular sociohistorical situation that makes their joint action possible and purposeful. Thus, the researcher who wishes to compare the normative statements of two competing ideological trends must himself, as historian, sociologist, economist, psychologist, etc., find out *which unstated premises of action are common and which are specific* to each competing group. It is not in the interest of ideologists to bring to attention the historical conditions of their normative proclamations. Rather to the contrary, they tend to stress any timeless, universal, or a priori character of which they can conceive.

6. It is a peculiar feature of our time that one positively loaded slogan is common to all powerful ideological groups and does seem to express more than mere positivity: it is more than a synonym for "good." This slogan is the term *democracy* and closely related derivatives.

7. Because of this slogan's universality, an inquiry into doctrines set forth as expressing democratic ideology is a convenient point of departure for the study of possible common features of all dominant ideological trends of this era. This method of study does not assume a priori that a common slogan implies the existence of a common belief.

8. Any formulation of universal ideological trends must be *prefaced by warnings*: the formulation presupposes successful clarification of linguistic, particularly semantico-terminological, confusion. It presupposes the even more difficult task of finding and *formulating implicit premises* of programs of social action. No individual or group can claim more than to give tentative, ad hoc conclusions on these matters.

9. The Lincoln formula affords a convenient point of departure for the analysis of ideological agreements on a "democracy." There is general agreement that to serve the people in the broadest sense of the term, and ultimately the people of the Earth, is the sole justification of government. Further, it is generally agreed that the people are served when each individual is given the fullest possible access to the means by which he can develop his own possibilities without jeopardizing the chances of others.

10. There is general doctrinal agreement that government should be "by the people," that is, that one should develop the most intense and widespread participation of the inhabitants in preparing, reaching, and carrying out decisions of importance to the welfare of the community. It is also agreed that such participation is possible only if a minimum of general education and leisure and energy is available for studies of the issues brought before the people. It is further agreed that in times of severe crisis, popular participation must be more or less reduced and opportunities of incitement to violent change of form of government curtailed.

11. From the unanimity on the principle of equal possibility of access to economic, educational, and cultural values flows an agreement that no individual should be allowed, by his particular talents or shrewdness, to reduce others to permanent dependence on him or to reduce permanently their and their offspring's access to economic, educational, and cultural values.

12. From the generally accepted broad interpretations of "people" flows a general rejection of race or color discrimination and a rejection of discrimination on the basis of religion, philosophical inclinations, or nobility of birth.

DEMOCRACY, IDEOLOGY, AND RATIONALITY

13. Implicit in the doctrines of government by the people and the appeals to knowledge as the guide in solving questions of policy, is a rejection of leadership on the basis of mystical insight of elites, of a *Führer* and *Gefolgschaft* following “the instincts of the pure blood.”

14. There is no indication of disagreement on the opinion that, in all ideological camps, people who sincerely accept the foregoing doctrines try to live up to their severe requirements and deplore the shortcomings of achievements so far realized.

15. The agreements thus listed make it possible to formulate severe criticism without leaving a common ground of accepted doctrines. The basic criticism will be that of inconsistency.

16. Even if the view were accepted that mere lip service to the *common aspirations and principles* is the rule and sincerity the exception, their codification and the *increasing frequency of appeals to them* the world over by individuals and institutions on the national and international level give to those who wish to propagate their sincere acceptance *a unique instrument* that should be tentatively perfected by research and worldwide educational drives.

Ideology and Rationality

Neutral and Negative Definitions of Ideology

Definitions of the term *ideology* may be grouped in two main classes, those that imply a negative evaluation, such as “there is something rotten about any and every ideology,” and those that are roughly neutral. The first class, which treats *ideology* as a dyslogism, may be further divided into two subclasses: definitions that stress illusion, preconception, fanaticism, mistakes, or narrowness, but *not* insincerity, and those that *do* refer to insincerity, bad faith, rationalizations in a Freudian sense, distortion, concealed interests, or naked power orientations. Most of the couple of hundred definitions provided in a previous work (Naess et al. 1956) conform to such a classification into neutral or negative definitions.

Rather than starting out here with a dyslogistic normative definition of the terms *ideology* and *ideological*, I define *political ideology* in a roughly neutral way, as for example has been done by F. Gross (1971: 5): “A political ideology is a system of political, economic, and social values and ideas from which objectives are derived. These objectives form the nucleus of a political program.”

Perhaps the term *system* in this definition might be dropped in favor of *aggregate* or *conglomeration*, since “system” suggests a rigid rather than a loose connection between parts of the ideology.

Political ideologies are predominantly rational and objective in various

This article was reprinted, with changes, with the permission of Kluwer Academic Publishers from *Ideology and Politics*, edited by Maurice Cranston and Peter Mair (Alphen aan den Rijn: Sijthoff, 1980), 133–42.

senses. Intersubjectively and interculturably testable, *sachlich*, their ideas may be true or false, valid or invalid. In principle, a scientific theory may be a mass of mistakes, as in the case of modern cosmology, but it is nevertheless objective. The same applies to testable ideas in general. However, ideologies are only *predominantly* rational: there are degrees and there are exceptions.¹ Nevertheless, the more or less controversial exceptions should not color the metatheory of political ideologies. As metatheorists, conducting *descriptive research* on political ideologies, we influence political life in different directions according to how we speak and write about political ideologies. The present paper is thus partly motivated by a desire to contribute to the partial rehabilitation of political ideologies from derogatory pronouncements made by political scientists and other groups of “intellectuals.”

Empirical Tests of Rationality

The rationalist and objectivist thesis has an empirical foundation. Widely known material in support of the thesis was collected by UNESCO from 1948 to 1949, when—with the superb collaboration of Stein Rokkan—I led its project on the ideological controversies between East and West concerning democracy. I shall have to describe the project in order to illustrate what might be called successive approximations to rationality through debate.

UNESCO invited about four hundred political scientists and well-known defenders of political creeds to describe their views on ideological and controversial issues at the beginning of the Cold War. A long and complicated questionnaire was duly answered, sometimes in the form of carefully written articles. Excerpts from thirty-three answers,² together with an analytical survey, were subsequently published. The resulting book was immediately sold out and never reissued.

I shall now convey a crucial lesson of the project. Each answer was mimeographed and sent to the other participants. Critical and polemical sections were commented upon, and in some cases we were able to organize a series of dialogues between fierce ideological opponents. The contact sponsored by UNESCO led to successive clarifications of disagreements and to the elimination of misunderstandings and unnecessary rhetoric. Although the dialogue sharpened some of the disagreement, and although

contrasts became more sharply defined, nevertheless the whole process served to increase the level of rationality and objectivity. When one unambiguously stated opinion contradicts another, both cannot be true. Mistakes, however, do not automatically reduce rationality. If they did, science would have to be classed as irrational.

Accusations of *Unsaublichkeit*, of motivational distortion, and of all the other features that push political ideologies into cognitive disrepute were weakened or tended to disappear. On the whole, the sharp disagreement concerned *testable hypotheses*. This holds true if we do not suggest more severe requirements of testability than are adopted by sociology, history, or cosmology.

Whereas much of the UNESCO material is published in some form, my second batch of empirical material is largely unpublished, or accessible only to those who read Scandinavian languages. In short, it is the formulation of, and the debate concerning, what has been called green political ideology. It is not a very definite group of ideas; rather it is a family of related and very broad views that fit exceptionally well Gross's definition of ideology.

Deep Value Priorities in Ideology

In political ideologies, political objectives and programs are derived both from deep-seated value priorities and from hypotheses about the world. For example, a decrease in or freezing of the material standard of living in the rich industrial countries is proposed as an expression of world solidarity, not just for reasons of resources, or to avoid north-south confrontations, or because the recent increase in the material standard of living does not seem to have increased the well-being of the average human being. This proposal is *in part* motivated by adherence to "universal solidarity" as a deep value priority, and to its realization as a hypothesis through politics.

A second example can also be drawn from Green ideologies. Concepts relating to an increase in the quality of life are advocated on fairly philosophical grounds in order to supersede those related to the standard of living. From this new value priority, new objectives are derived that contrast with traditional social-democratic views. Indeed, the social-democratic government in Norway has been provoked to put forth a political program

for 1978–1981 that takes notice of the value debate. Eight main goals of its policy are formulated, and its concrete political proposals are worked out as a consequence of the value priorities' acting as normative guidelines.

A third example concerns how a higher regard for the needs of future generations—resources, clean oceans, diversity of cultures and ecosystems—clashes with prevalent priorities. The justification for this new approach requires depth of argument and touches the levels of philosophy.

Of course, there are many other examples from many parts of the world that show the vigor of political ideologies operating on a fairly high level of rationality combined with deep value orientation. “Deep” in this context refers to chains of argument: “Why *A*? Because *B*. Why *B*? Because *C*. Why *C*? Because *D* . . . ,” and so on. The farther such chains extend, the “deeper” are the questions and the answers.

A major question remains concerning the intersubjective and intercultural testability of value priorities. How can a *proposal* for increased global solidarity be tested for goodness or validity? This depends on the arguments for the proposal. It is largely an empirical question as to which arguments actually are used by those who defend an ideology, and it turns out, on the whole, that the weight and relevance of the arguments are testable. In the present case, for example, while it may be difficult to test some of the arguments concerning a decrease in north-south confrontations, it is nevertheless not impossible. The argument that overconsumption in one part of the world in the face of hunger in other parts of the world contradicts the ethics that most consumers wish to practice, is itself testable. This argument does not proclaim the validity of an ethic, but the ideology is, after all, a political one, and not a complete system comprising ethics. The argument is testable as a hypothesis about wishes and consumers.

Value-oriented arguments against Norway joining the European Economic Community were based on highly testable predictions, as were the arguments for EEC entry. Both sets of predictions, in the form in which they were stated in the mass media, have now been tested and, on the whole, confirmed. Some of the more carefully worded predictions remain either untested or unconfirmed. In any case, it is not warranted to complain about an essential lack of testability in such value-oriented arguments.

In short, a proposal is good in relation to its value statement, and the value statement is tested by asking what the value is supposed to be valu-

able for. There are hierarchies of aims and goals, and therefore of rules, of norms, and of values. In ideologies, as in scientific research, rules and values have no definite ultimate foundation. Or if they do have, such as with the basic rules of inference in a system of logic, there are limits to testability. Without trying to take up the philosophical problems encountered here, I contend that such a limitation does not justify a denial of rationality.

As already indicated, however, ideologies do differ in this regard. A distortion of problems may take place, for example, as is ably argued by Raymond Aron (1957: 239–40): “Sometimes the [ideological] debates truly reflect the problems which a nation must seek to solve, sometimes they distort or transform them in order to fit them into would-be universal patterns.” The *intercultural* testability is realized insofar as the special conditions within one nation or culture can be described so that they are roughly comprehensible to outsiders. In other words, there is no difference in principle that makes “foreign” political ideologies inaccessible to research on ideology.

The Irrationality of Our Opponents’ Ideology

There are certain misunderstandings that contribute to the view that political ideologies either are irrational or function irrationally.

1. Violent clashes of will and crude confrontations are taken as proof of the irrationality of the sets of ideas of the combatants. Certainly, if the will to compromise is lost, political confrontation is likely to follow, but this may be taken into account in a rational fashion within the ideologies: “if they do not accept our proposal, we shall win.” Thus, the fight itself is not part of the ideology.
2. We attribute blindness, partisanship, and closed-mindedness to our ideological opponents, and since we do not regard ourselves as ideologists but as being politically open-minded and reasonable, accusations are then turned upon ideology in general.
3. We occasionally tend to identify the ideology of our opponent with his slogans and catchwords, or with the least defensible of its versions, whereas we select carefully what we are willing to identify as the views of our own group or party.
4. The closed-mindedness of our opponent is conceived as being typi-

cal of his ideology. In fact, it may owe largely to his having already heard most of what we tell him. He has already decided that our view is untenable, and therefore he is impatient and will not listen. The simple explanation for his stubbornness may be unconvincing to us, because we feel sure that *if* he really listened carefully he would change his opinions—or else we have to consider him stupid or dishonest.

5. The alleged fanaticism of our opponent or his stand has a similar genesis. Here, though, a set of rhetorical rules of the political game is relevant. Suppose, for example, that a policy is *defended* by a dozen pro-arguments and by a dozen arguments against counterarguments (“cc-arguments”). Then the rhetorical game is such that no admission of the slightest relevance or weight of a main counterargument, or a ccc-argument, is acknowledged without an immediate proclamation of the superior relevance or weight of a corresponding cc-argument or cccc-argument. So, within the framework of this game, no concessions are granted. Given a negative attitude toward the opponent or his stand, the rules of the game are falsely attributed to close-mindedness and/or fanatical beliefs. The negative conclusions are subsequently transformed into derogatory utterances about ideologies.

6. The overwhelming complexity of political considerations makes it necessary for a politician to rely heavily on intuitions in forming a policy. However, the rules of the game demand that, if pressed, he should be able to furnish arguments. It seems that, lacking real arguments, he might resort to anything, however irrelevant or trivial, but the way in which the “answer” is provided suggests that the policy defended is largely independent of the support of those so-called arguments.

Ingroups and Outgroups

An exact comparison of expressed doctrines requires distinctions in terms of ingroups and outgroups. There is an ingroup version made by the adherents of doctrine *A* describing itself and doctrine *B*, and an outgroup version of doctrine *A* described by the adherents of *B*. An important job of the researcher is to explore the possibilities of reducing these differences in order to arrive at a single version of each doctrine. This job is essentially the same whether one is comparing trends or schools in social or natural science.

What if the reduction of one version is impossible without changing

the very opinions of the adherents? What if the mutual image (for example, the communist image of anticommunism and vice versa) is an essential part of the ideologies?

The conclusion is *not* that there is a kind of basic irrationality at hand, or that we encounter irreducible perspectives when structuring the world. The conclusion is rather that the argument of one group does not convince the other group. This was a main conclusion of the UNESCO examination of the East-West ideological controversies on democracy. Some opinions are changed through dialogue and added information, but in most cases this is not adequate to the task of changing the essential parts of an ideology.

An important ingredient in descriptions of outgroup opinions is the hypothesis that the outgroup says one thing but means another. The outgroup says that it favors protecting small business against big business, but it really does not mean this. The outgroup answers that it does *really* mean it, and that the ingroup (*A*), which is its (*B*'s) outgroup, only accuses *B* of duplicity in order to discredit it. Group *A* really understands that group *B* sincerely means to protect small business.

The situation resembles that of the experimental theory of learning in psychology. The different schools—one led by E. C. Tolman with Berkeley as a center; the other, by C. L. Hull presiding at Yale—engaged in a debate in which one class of disagreements touched the very opinions of the contestants. Tolmanic views about what Hullian theory of learning actually *asserted* differed consistently and permanently from the ingroup view, and vice versa. The disagreements were never resolved. Although some might say that this shows the irrational character of theories of learning, it should be noted that essentially the same situation holds in debates about the so-called Copenhagen interpretation in quantum physics.

Clearly, any debate carried through in all seriousness may end without any major concessions from either party. This in itself, however, does not imply irrationality, bad faith, or different basic perspectives on the world. There may indeed be honest disagreement; for example, as to the *priority* of protective measures for small business under various circumstances.

The goals or values of a political program are always in conflict with one another, in the sense that maximum satisfaction of one implies less than maximum realization of another.

The maximum *persuasive* power of representation requires the presentation of a program to slur over the mutual conflict of goals and values. The maximum *convincing* power of representation requires difficult, complicated, and bulky presentations, unsuitable for mass communication. In practice, one has to meet the politicians in more or less “closed” sessions to get hold of some of the most satisfactory formulations from the standpoint of descriptive research on ideology. (In this paper I have that kind of research constantly in mind.)

I say “some of the most satisfactory formulations” because versions that are cognitively less satisfactory but nevertheless more effective are important to the understanding of how an ideology actually functions and also of how the politicians wish that it should function. They do not usually regret the effects of certain misunderstandings arising from vagueness, ambiguity, or the concealment of conflicts between goals.

The End-of-Ideology Movement, *Ideologiekritik*, and Hermeneutics

The reaction against very vague and very general political convictions is sometimes carried too far, as can be seen in the end-of-ideology movement. Raymond Aron, in his justly famous work *The Opium of the Intellectuals*, fought the “myth of the left” and “the myth of the revolution,” but he did not stress the need for deep, value-oriented ideologies that can cope with deep political, national, and global problems. Moreover, after his scathing criticisms, what did he then put forth as valid political goals for France? “To organize a genuine community between Frenchmen and Moslems in North Africa, to unite the nations of Western Europe, so that they are less dependent on American power, to cure the technological backwardness of our economy—such tasks as these might well arouse a clear-sighted and practical enthusiasm” (Aron 1957: 317–18). Today, a political ideology worthy of enthusiasm would have to dig much deeper.

It is an unfortunate misconception that the degree of fanaticism must be in proportion to “deepness.” On the contrary, an awareness of the immense distance between ultimate premises and concrete proposals for action in a definite political situation is a protection against fanati-

cism. In the long term, this awareness is something that can be fostered everywhere.

The *Ideologiekritik* movement in Germany has contributed to the interest in close relations between political views on the one hand, and vested interests, social position, and economic system or, more generally, means of production on the other. It has stressed bad faith, distorted communication, and other phenomena referred to in negative definitions of ideology. Unfortunately, *Ideologiekritik* has rarely been carried out in research programs with adequate methodological tools.

The same holds for hermeneutical and holistic interpretations of ideology, which stress basic differences in ways of understanding the world and subsequent basic, more or less insuperable differences in political language and views. Here, an overreaction against logical positivist views seems to have reduced the interest in plain descriptive comparisons of existing ideological trends.

Doctrines stating that political ideologies are irrational promote irrationality in politics. They tend to have a slightly self-verifying character. In Scandinavia the political philosophy of *Ideologiekritik*, and especially the inclination to look upon social-democratic ideology as a mere reflection of means of production or naked power constellations, has made it difficult for young people to take their opponents seriously, and thus led them to favor confrontations rather than serious debate. There can be no sincere debate when the opponent's way of understanding the issues is considered to be determined by his social position.

Conclusion

In conclusion, I would like to stress that the views defended in this paper are consistent with a serious concern about the irrational features of present-day political ideologies. Nor do these views imply an overestimation of the causal weight of ideological considerations in shaping the world. The direction of development of the rich industrial societies may be largely independent of what politicians or others are thinking and saying. To a large extent, political actions may be considered as minor adjustments to trends that are out of control. Further, in spite of the vastness of govern-

DEMOCRACY, IDEOLOGY, AND RATIONALITY

mental organizations, their power over technological trends may be rather modest.

Having made this concession not only to irrational but also to all non-rational factors in political developments, I end with a plea for plain descriptive research on ideology. It bears repeating that such research tends to confirm the predominantly rational and objective character of ideologies and of ideological debate.

The Function of Ideological Convictions

What are the main influences on the development of national aggression? This and closely related questions are raised in thousands of speeches, articles, and books all over the world. The majority of authors write as if there were a solution, as if they knew the solution, and as if they believed the wording of their solution were fit for the communication of insight to other human beings.

Excessive Claims to Certainty and Finality in Writings on National Aggression

In some cases, the authors who write with certainty and finality do so without seriously believing that their solutions can in fact claim any certainty or finality; they word their statements as they do to conform to norms of eloquence and techniques of propaganda. In other cases, though, the preten-

The three articles in this section fit together as a seamless whole. They offer an overview of Naess's work on democracy and ideological conflicts, which began with his role as the scientific leader of the UNESCO Democracy Study. It was the first major application of his empirical semantics, after his creative Truth Studies (see SWAN VIII). The first article, which addresses the UNESCO project, originally appeared in *Tensions that Cause Wars: Common Statement and Individual Papers by a Group of Scientists Brought Together by UNESCO*, edited by H. Cantril (Urbana, IL: University of Illinois Press, 1950), 257–98. The second article gives an extended survey of responses by the experts consulted and offers Naess's important and controversial overview and summary of the agreements and disagreements among the participants. The third article carries Naess's work into a general discussion of the relationship between differing conceptions of rationality and ideology.

sions seem to be seriously meant and are so understood by those hearing or reading the solutions set forth. In these instances the “solutions” do not appear to be held in a tentative way but are set forth as nothing short of statements about reality as it *is*. The solutions—whether in terms of imperialism, struggle for existence, release of irrational impulses basic to human nature, hateful propaganda, lust for power, fanaticism, or religious or political faiths, or in terms of more complex factors—are set forth without qualifying phrases carefully describing them as more or less tentative but fruitful hypotheses worth testing.

To any man searching for reliable knowledge more than for inspiring faith, the certainty claimed for such solutions is excessively high. To profess belief in such degrees of certainty against the background of the grave shortcomings of basic research in these fields is incompatible with the discerning attitude required in any science of human relationships. This holds good even if we consider that the proponents may have felt a kind of moral or social obligation to combine a cool analysis of influences on national aggression with a plea for a certain ideology or political faith.

Moreover, the exaggerated certainty, preposterous expectation, and subsequent frustrations are not the worst features of the solutions from the standpoint of those seeking to avoid action based on misinformation. Still worse is the fact that the solutions are rarely free from gross slogans and catchwords.¹ In the search for reliable knowledge, clearly stated mistakes are generally more easily eliminated than foggy generalities lacking precise meaning, because the latter are not verifiable. That they are apt to stir the emotions and control the action of men is no disproof of their uselessness in the search for reliable knowledge. A few social scientists, for example, Bryce, have even hinted that the very lack of precise meaning is a prerequisite for mass control. That may not hold good for the future, however.

Education Should Stress the Hypothetical Character of Textbook “Knowledge”

If there is any important prediction that social scientists today can make with a fairly high degree of certainty, it is the following: in tackling the problems involved in an inquiry of the present kind, answers likely to

prove tenable and likely to embody fruitful working hypotheses will be highly conditional, complicated, and piecemeal compared with most answers so far given publicity.

We may safely make this prediction not merely as specialists in certain narrow fields of science but as men seeking knowledge rather than influence. If scientists could enlist a broad consensus for the tenability of such a prediction, the ground would be cleared for an appreciation of what research can do for human welfare at large. Expectations of simple solutions make it difficult to mobilize the energy and resolution necessary for people to work with and act upon complicated piecemeal hypotheses of admittedly limited certainty.

This principle is one of the few important things that may be stressed in a short survey such as this: we need to foster a critical attitude toward “general solutions” involving pretensions of finality. Such an attitude is a prerequisite of any program for the application of social science to the major problems of our time. To foster such an attitude should be a major goal of infant as well as adult education. The tender seeds of critical attitude cannot develop and give fruit as long as the sturdy weeds of unquestioned ideological convictions are, at the same time, permitted to grow undisturbed.

It is within our reach today to counteract the undesired consequences of the tendency to have either complete or no confidence in a statement. It can be done by reforms of elementary and higher education. Graduate students, and not just those in statistics and related fields, could be trained in the estimation of weights of hypotheses. Further, the level of popularization and mass communication can be improved by a shift of content from a mere description of hypotheses toward a description of hypotheses combined with critical weight indications. There is fairly accurate evidence that the weightings tend to be ignored or lost from memory. The result is disappointment because of misled expectations. Present-day textbooks, by and large, fail to satisfy these requirements and are thus a menace to the fostering of a critical attitude.²

Social Science More Effective in Reducing Pseudoknowledge Than in Building Up New Knowledge

I decided to begin this article with a warning against vague generalities and pretensions of certainty because any article dealing with a major aspect

of the question of this inquiry, and naturally also the present paper, will easily degenerate into just the kind of proclamation that I should like to see vanish from the earth. In a short survey such as this, there is no place for adequate argumentation and precise formulations. Thus, a paradoxical situation arises. If this article is read and its intention accepted, the reader might turn against it because it does not give what the general title indicates: a description of major influences on the development of national aggression. As long as we do not have a science of popularization and condensed description, only preliminary hints appealing more to readers' imagination than to their intelligence can be conveyed in an article like this. The numerous important but piecemeal findings of the social sciences cannot be dealt with adequately. Neither would these findings as yet in any way appreciably confirm the hypotheses that are formulated in the following pages. I think, however, that they are reasonably strengthened by everyday observations and may furnish fertile hypotheses for future research.

Concluding these introductory remarks, I venture to affirm that under prevailing societal conditions one of the factors that on the whole tends to bolster large-scale aggressiveness and to block the expansion of sympathy on the international level is the *excessive reliance on hypotheses about means-end relations of social and political importance*. Theological fanaticism and credulity of former ages have largely been displaced by social means-end credulity culminating in aggressive political ideologies. In this century the largest contribution of social science to peace might turn out to be more adequately described as the *liquidation of pseudoknowledge* than as the building up of new knowledge.^{3,4}

Scientific Information on Means-End Relations Is Unfavorable to the Development of Large-Scale Aggression

Let us consider the following hypothesis: the mass of present-day *tentatively* assertable working *hypotheses* on means-end relations and on the desirability of ends are on the whole less apt to motivate large-scale aggression than the mass of present-day doctrines making claims of unconditional acceptance.

Even if this hypothesis, which I think is tenable, is judged untenable by others, there is still room for belief that the social sciences may con-

tribute substantially to the understanding of controllable factors in national aggressiveness. However, I consider its tenability an important guarantee that scientific working hypotheses about means-end relations will not have the devastating effects sometimes attributed to the “relativism,” “cynicism,” and “positivism” of our era by men like Berdiaeff, Sorokin, and others. If the assumption is tenable, we have reason for optimism about the future services of social science; its beneficial influence may turn out to be largely independent of special social hypotheses. Even if they all prove more or less mistaken, a beneficial influence may result from the fostering of open-minded inquiry, of willingness to *modify* opinions, and of basic scepticism toward pretensions of the finality of conclusions in general.

The assertion that the prevalent excessive reliance on opinion, concerning the way in which desirable social conditions can be realized, tends toward national aggression and against international understanding needs detailed documentation. After surveying the very indirect relevance of existing research, however, we find that the best characterization of the situation is that detailed documentation is not possible today.

What we should like to establish in this paper is, not so much the hypothesis of an objective, absolute norm of justice that might be taken as an aggressive belief, but of beliefs (1) that some outgroup violates justice, (2) that justice can be restored by punishing or annihilating the outgroup, and (3) that the ingroup can or even has the duty to do this. Thus, we do not so much fear the existential formulation “There exists an objective justice” (in most plausible precizations of that formulation), as formulations of the kind “We have objective justice on our side in our fight against the others” and “Our ruthless fight against them can reestablish justice.”⁵ In short, it is the attempt to *apply* principles, not the belief in principles, that is dangerous. Our concern is with this means-end form of absolutism, not with *any* kind of absolutism. We are not concerned with statements such as “God is” but rather with “God is *with us*.” Clarity at this point is of importance to the interpretation of the main theses of this article.

There is a passage in Russell’s *Freedom and Organisation* (1934) that illustrates the above distinction: “Mazzini’s conscience told him that England ought to intervene on the Continent by force of arms to secure freedom for oppressed nations, Cobden’s conscience told him the exact opposite. Both were earnest and highly moral men. Two men who both accepted the prin-

ciple of utility could argue about their practical differences, since they had a common standard, but two men who both followed the 'law of God' and found that they differed could only accuse each other of wickedness and fight it out. Thus Mazzini's ethic, which sounds so much nobler than Bentham's happiness principle, becomes, in its application to practical affairs, nothing better than the rule of the big battalions."

Mazzini scarcely believed it to be a law of God that England ought to intervene on the continent by force of arms, but he might have believed that such an intervention would be in accordance with a law of God, that it might be an application to a concrete case subsumable under a more or less general law. Now, however, there is no difficulty of principle that prevents peaceful discussions on the *applicability* of a law to concrete cases, however holy that law may be.

If both Mazzini and Cobden were absolutely convinced of Bentham's happiness principle but made with complete confidence opposite application of it to the question of English intervention on the continent, such a situation might perhaps just as well lead to a "solution" by big battalions as would exactly opposite views based on moral intuitions and alleged laws of God. The basic issue would be their confidence in their own conclusions, not the kind of principle adhered to.

What Russell, in our view, might say in favor of the happiness principle is that *attempts at rational application* of that principle to concrete cases more probably lead to solutions held as tentative working hypotheses than do attempts at application of theological principles. Our thesis is not that national aggression would no longer take place if means-end hypotheses were properly weighted and action were based on the result. We only predict a decrease in trends toward such aggression. A more radical statement of the thesis is hinted at by Hitler when he says that *only* "fanatical belief" of some kind can make men find it justifiable to use "the most brutal weapons" for their aims.

Does a Critical Attitude Make for Indifference in the Face of Aggression?

Some might well agree to the assertion that tentative working hypotheses constitute an unfavorable basis for inducing men to join programs of large-

scale aggression, but might at the same time be prone to maintain that attitudes fostered by research are unfavorable to every large-scale effort and are therefore unfavorable to large-scale resistance to violence. A critical attitude fosters indifference, it is said. "Doubt weakens the will." The behavior of interval Social Democrats in Germany is often cited as evidence of how people highly educated in self-criticism and means-end opinions are unable to halt waves of aggressive opinion. To oppose effectively such waves and to motivate protracted and intense action in general, people need strong, steady motivation. The cool weighting of science undermines and makes impossible such behavior, it is maintained.*

Here we touch a basic point concerning the function of scientific information on the one hand and the function of contemporary ideologies on the other. We shall therefore try to word our point of view somewhat more carefully than usual in this article.

A distinction must be made between faith in ultimate ends and values and faith in ends that we accept because of the relation they are supposed to have to ultimate ends and values. Social science has by definition nothing to say directly for or against any value judgment that we deliberately pose as an ultimate premise to all or a certain part of our means-end thinking.⁶ *There is no inconsistency between a strong will to realize an ultimate end and extreme criticalness toward each particular means proposed as conducive to that end.*

If a man or a rat is hungry and uncertain about how to get food, this may induce him to energetic action in various directions. The man will normally form verbalized hypotheses that are tried out, one by one. Roughly speaking, the hungrier both are, the more energetically they will try out various means. To generate and maintain eager search, it is not necessary to be absolutely certain of the reliability of a particular means-end hypothesis—for example, one stating that a certain alley in a labyrinth leads to food.

The belief that only unconditional acceptance of hypotheses can moti-

*Against the use of the argument concerning interval Social Democrats to support this thesis it may, for example, be argued: There was among them uncertainty about fundamental aims rather than about means. There was even acceptance of ideological doctrines teaching that evaluation is "unscientific," that no value judgments can be derived as conclusions from premises expressing knowledge.

vate strong action is frequently mixed up with certain beliefs about the "crisis of our age." The extreme success of Western society in procuring means to greater production and to a higher material standard of living has turned attention away from ends and their hierarchical order, thus leaving many people without those steering mechanisms that only clarification of means-end relations and faith in ultimate ends can furnish. In saying that Western society has been successful in procuring means rather than ends, we wish to indicate that it has been particularly successful in procuring what has nearly universally been thought of as instrumentally, rather than ultimately, valuable. Without some basic conviction about which ends and values are lofty enough to be accepted as ultimate, the critical attitude toward means-end hypotheses will result in a lack of motives for strong and protracted action. This will hardly be denied by anyone. Then, however, the so-called crisis of scepticism and relativism is not necessarily caused by a critical attitude toward social means-end hypotheses but may owe to unawareness of norm hierarchies and to the consequent lack of steering mechanisms for social behavior.

Thus, the above argument may be answered by the assertion that wholehearted *belief* in ultimate values *in addition to critical and tentative* acceptance or rejection of means-end hypotheses can make up a motivational basis for intense and protracted action. Metaphorically, our argumentation can be reformulated thus: a cool head can never make up for a warm heart, but neither can a warm heart take over the functions of a cool head. Cool-headed manipulation of questions about *how* to realize basic values is necessary to successful action on their behalf.

There is a relation between the state of alarm and tension within a society and the limits of socially approved critical-mindedness. The limit is narrowed down in times of supposed crisis, and above all during wars. One of the reasons for these attempts at crippling man's capacity for intelligent deliberation seems to be the fear of decreases in the intensity of motivation. To continue the metaphor, the reason that tentative means-end thinking is tabooed in wartime is not so much the fear that it will weaken the will of the coolheaded as the danger that it will reduce the efforts of the muddleheaded and of those who are cool at heart; the capacity to act on uncertainties is not judged to be very widespread. The question of whether such a taboo is an effective means for military or other ends can only be answered by future research, not by speculation or propaganda.

Is Social Science Allied with “Nihilism” and “Relativism,” and Does It Thereby Contribute to the “Crisis of Our Age”?

It is the opinion of millions of people that further development of science will aggravate the present moral crisis and that its position in a future society will be less dominant than it is today. A future stage of humanity is believed soon to be reached, which will be characterized—as the European Middle Ages were—by firm, nearly universally held convictions on fundamental ideological principles as well as their applications. Empirical methods and even empirico-scientific criteria of truth would be disregarded or used within much narrower limits than today.

We mention this kind of interpretation of the “crisis of our age” because many contemporary social philosophers and some sociologists have developed similar doctrines. A conspicuous example of the latter is Pitirim A. Sorokin (1941: 231ff), who predicts that within the framework of the contemporary (sensate) culture, society, and man, no elimination, even no substantial weakening of group tensions—economic, racial, ethnic, occupational, and others—is possible. In a future framework, the weakening will be affected by forces other than social science.

When social science is made responsible for or considered typical of “decadent” Western thought, this cannot reasonably be justified by pointing to the absence of fundamental norms proclaimed as valid by assertions within social science. Justification of such norms would lie outside its scope, just as it lies outside the scope of artistic activity. To this most scientists agree, but whatever the basic evaluations may be—whether religious or nonreligious—there is need for research on means-end relations. If no misconceptions about the scope of the sciences are used as premises, it is difficult to see how one can arrive at the conclusion that social science is detrimental by its “relativism” or “nihilism.”

Ideology and Ideology Research

The above argumentation leads us into the difficult realm of ideology research, a convenient name here used for research on highly stable clusters of opinions, believed by their adherents to represent coherent doctrines capable of justifying group action. In cases of political action, we speak of political ideologies.

The word *ideology* has never designated any well-delimited class of phenomena. It has a slightly dyslogistic function, comparable with but probably less intensive than the word *propaganda*. As here introduced, it may roughly be said to comprise both ideologies and utopias in the terminology of Mannheim. As used here and by some other authors, the ideologies or, in a more general way, ideological doctrines consist of clusters of (1) ethical or social norms or principles and detailed codes of behavior; (2) politically relevant hypotheses, especially means-end hypotheses; and (3) verbal stereotypes with no fairly precise meaning, but influencing controversies within and between nations.

The ideological doctrines are normally set forth with emphasis on certainty and finality, and they claim to command respect in the way that religious faiths usually do. As examples we might take argumentation patterns in defense of capitalism, the liberalism of John Stuart Mill, Marxism, syndicalism, Leninism, fascism, anti-Semitism, and the Americanism of the Thomas committee.⁷

Ideologies play a decisive role in the mobilization of public opinion, a process of vast importance in preparations for modern war. We shall, therefore, take a brief look at the field of ideological research viewed as a part of future social science.

One of the objectives of social science is to describe and classify ideologies in terms of their doctrinal contents; another aim is to "explain" them in terms of their function in society: how and why they are built up and how and why they change in correlation with economic, social, and cultural factors. A classical work like Dunning's on the history of political theories serves the former aim to a large extent. Series of works of Hegelian and Marxian inspiration attempt to serve the latter. Among the notable works in the latter field may be mentioned Charles Beard's *Economic Interpretation of the Constitution of the United States*.

The vast majority of publications on ideologies are themselves partisan descriptions. They are mainly concerned with "goodness" or "badness" even if masquerading as pure descriptions. Nonpropagandistic study of ideology is an almost virgin field. It can be extensively cultivated only in societies in which social pressure against disconformity with the dominant ideology does not intimidate researchers and those responsible for their financing. This requirement excludes practically all contemporary societies.

The following are some keywords (not necessarily expressing doctrines) having important functions in ideological controversies and crusades. We mention them just to remind the reader of the vast infiltration into social life of faiths and doctrines defended as indisputable by some people. We have, for example, Americanism, anarchism, anti-Catholicism, Aryanism, Catholicism, Christian democracy, fascism, humanism, individualism, internationalism, liberalism, my duties as a good Afghan (Australian, Austrian, Belgian, Bolivian . . . Venezuelan), nationalism, Nazism, nonviolence, Nordic way of life, planned society, positivism, radicalism, relativism, scientific attitude, socialism, syndicalism, the rights of the individual, and the system of free enterprise.⁸

The slogans listed here stand for complexes of valuations and descriptions intricately and vaguely intermingled. For example, anti-Semitism may, as an ideology, be said partly to consist of *descriptions* of supposed characteristics of Jews as a more or less vaguely delimited class of persons. Further, it consists of doctrines stating *how* Jews may be eliminated from having the influence, etc., they are supposed to have. These descriptions are means-end hypotheses. Lastly, there are in anti-Semitism as an ideology more or less implicit norms: valuations justifying the elimination of Jewish influence and condemning the characteristics attributed to them as being of negative value. Sometimes these norms are such as are held by most people, whether anti-Semitic or not: for example, the norm "You should not cheat." In such cases, it is the strong belief that certain groups violate the norms, and the manner in which that belief is held—for example, moral condemnation of doubters and scorn for unbiased investigations—that makes us class the beliefs as ideological.

In other cases it is rather the value judgments that are characteristic of the ideology. Thus, in fascism fighting as such, apart from goals, is considered a value; and in anti-Semitism, we find the norm that race discrimination is socially and morally justified.

Given the prevalence of descriptions and means-end hypotheses, scientific research is highly relevant to the acceptance or rejection of ideologies. The likelihood that an ideology resting on uncritical assumptions and prejudices will prevail will diminish perceptibly if research and dissemination of its results are given free scope. This may be one of the reasons that the scientific attitude is so much distrusted by people strongly believing in the elements of their descriptive ideologies.

To What Extent Do Ideologies Function to Organize and Justify Aggression?

The expressed contents of an ideology are important for its aggressive potentialities. If an ideology glorifies national conquests and wars, its influence must of course be expected mainly to be toward national aggression. Even if an ideology does not openly advocate aggression, however, it may be apt to foster militant views likely to prevent nonviolent settlements of disputes. Certain features of Buddhist and Christian ideological patterns are expressly nonviolent and favor consistently nonaggressive modes of settling conflicts, but considered as wholes and viewed in the context of their function in the life of societies, they are among the dominating ideologies that stress the wickedness, injustice, and inferiority of outgroups and that use hatred to pave the way for violence.* Political and social ideologies, *as they operate today*, seem to be instruments of organizing hatred rather than benevolence. Religious ideologies that cherish nonviolence in theory may function to reinforce the trend toward violence at times when political ideologies have contributed to the creation of a sufficiently tense atmosphere. This function may be studied by content analysis of preachings before and after declarations of war. There are, on the other hand, many examples of the opposite function of religious ideologies: that of reconciling conflicting groups. Thus, the Norwegian State Church that in 1945 strongly supported the large-scale punishment of quislings has more recently worked for less aggressive treatment.⁹

Aggressive intentions release more energy for efforts of justification and rationalization of action than do benevolent ones. Thus, the technique of building up impressive superstructures of principles and means-end doctrines is to a large degree used for the rationalization of demands that seem most easily satisfied by fighting or oppressing other peoples. Benevolent intentions do not need elaborate ideological superstructures.

We have already tried to establish the point that the exaggerated certainty of means-end hypotheses, and the invocation of moral indignation in case their certainty is questioned, on the whole works toward violence, non-cooperation, disbelief in arbitration, a high-handed attitude toward new information, ignorance of the opposition's view, and self-righteousness.

*As forms of violence, we class any use of physical compulsion.

Closely related to the blinding influence of absolute convictions is the influence of thoroughgoing vagueness and ambiguity in preventing any testing and any formation of coherent doctrine. If opinions are couched in sufficiently vague and ambiguous slogans, the absence of meaning is not perceived, and they may be used rather independently of whatever happens. No testing is possible when nothing definite is described or predicted, so whatever is found to be the case the adherents may stick to their “faith.” This means in practice the reinforcement of certain patterns of action that are habitually associated with slogans.

The Function of Ideologies in Cementing Ingroups and Making Outgroups Seem Remote and Wicked

How can thoroughgoing, vague, and excessive claims on certainty be upheld in an age said to distinguish itself by “scepticism” and “relativism”? How can such claims survive in the face of the rising prestige of tentative working hypotheses in natural science and the world of technical knowledge?

Much can be learned here from research on the effectiveness of commercial advertising, on propaganda and suggestibility. The applicability of many findings in these fields would not be contested—except when applied to the particular ideological patterns supported by the subjects asked.

For present purposes, some of the findings may be summarized as follows:

1. Mere repetition of a slogan tends under many conditions to make it more acceptable, that is, tends to reinforce patterns of action that those promoting the slogan wish the public to display.
2. Expression of firm, unshakable conviction on the part of the promoters of a cluster of opinions tends generally to enhance the effect—even if the public in reflective moods does not think the opinions plausible.
3. Sentences set forth by the promoters in a manner and in a context suggesting that they are fairly precise assertions, may be reacted upon as if they had those characteristics, even if closer analysis reveals a high degree of vagueness and ambiguity, making them unsuitable for rational discourse.

DEMOCRACY, IDEOLOGY, AND RATIONALITY

There are, however, features of commercial propaganda and advertising that limit the use one can make of them for understanding how ideologies are believed in and fought for. All manufacturers of, say, beer or radio sets have interests in common that are clearly seen and that in part explain the moral codes forbidding direct attacks on each other's products. There may be common interests among absolutist ideologists too—I think they are important and make “consumer research” of ideologies very desirable—but the common interests are inconsiderable and difficult to analyze. This makes it profitable for the ideologists to exploit an extremely potent realm of antagonisms not available to the commercial advertiser. It is commonly held by students of social and political movements and by historians that antipathies can be more easily evoked and are more powerful stimuli for action than are sympathies. However difficult it would be to confirm such contentions in a fairly precise way, what at least seems clear is a prevalence of “anti-” content in most ideologies. They are tools for fighting *against* something rather than *for* something.¹⁰ They create outlets for aggression rather than for cooperative behavior.

To understand better the function of ideological convictions it is useful to examine some hypotheses on the function of ideology in intergroup conflicts. The hypotheses are usually accepted as adequate as long as they are made to bear upon ideologies other than those toward which one is himself sympathetic. Hitler is one of the few who admitted some of the functions of ideologies to hold good even of his own tactics.

Suppose a large number of people find that they have some basic interest in common for which they are willing to fight, in the sense in which pressure groups and parties can be said to “fight.” If the group is to act in an organized, persistent, and determined way, it is important to consolidate, to *gleichschalt*, it, to make its members aware of a common and strongly demarcated frontier toward people of opposite interests. The narrowness of vision that seems to be a requisite for joint action by large, unevenly informed masses can be maintained only in this way. It may also be necessary to make some people join the action who do not have a strong interest in common with the others. Now ideologies and all sorts of isms and stereotyped catchphrases with strong and persistent emotional associations within the group are highly adapted to the purposes of consolidating and enlarging the ingroup and creating hostility toward the outgroup. The

members of the ingroup get a platform that they share and that they can cherish as a common basis for *justified* action. A cleverly distorted picture of the outgroup provides the maximum of justification for fighting it.

All differences between ingroup and outgroup must be strongly emphasized and therefore tend to be grossly exaggerated. For this purpose, tendencies to give fair statements of the views of opponents are thwarted and regarded as acts of treason or signs of weakness. Of special importance is the slanted description of morally relevant traits of the outgroup. Attempts at fairness tend to be scorned as indicating lack of loyalty, hairsplitting, or lack of devotion to the great cause. To make schisms appear simple and straightforward, it is important to slur over the structure of the outgroup, so that it looks like one compact homogeneous group. Public attention has lately been drawn to this trick because of the worldwide misuse of words like *democratic*, *communist*, and *fascist*.¹¹

Consolidating and fortifying the ingroup is likely to require a vague phrasing of the program or faith; in this way ingroup differences can be downplayed. There may be precision only at crucial points referring to action: for example, "Vote for Mr. X." This precision we usually find when particular measures are to be taken against outgroups.

The above description of some aspects of how ideologies are built up in the verbal warfare of groups would probably be subscribed to by most people in the abstract, but would be differently applied in concrete cases. It has become fairly clear that even allegedly nonpartisan institutions such as the Institute of Propaganda Analysis have tended to "discover" trends toward distortion only in some groups, and that that did not include groups represented more or less indirectly by the institute. Thus, the eagerness to accept any "debunking" views on ideology is considerable, but implicitly it is accepted only as describing adversaries. What is needed in this grave situation is a fairly exact science of controversy and ideology construction, so well based on relevant observation that conclusions cannot easily be dismissed as biased. As long as there is no such science, analysis of controversy and ideology will itself continue to be biased and partisan.

The analysis of ideologies as they function in consolidating ingroups and alienating outgroups cannot be undertaken by persons belonging to either the ingroup or the outgroup. Even when the analyst is independent of group loyalties, it is a complicated job to disentangle gross exaggerations

from fairly unbiased descriptions of differences of opinion. To accomplish this job, we need the tools that are being worked out under the name of "content analysis." It is adapted to the situation in which members of one group give distorted rendering of the opinions expressed by members of an outgroup, for example, a slanted newspaper report by group *A* of what a leader of group *B* said in a certain speech. So far, content analysis has been used to study relatively simple structures, but it may in time prove useful for ideology analysis.

The Tendency to Exaggerate the Philosophical Profundity of Ideological Conflicts

The doctrine of Marx and Engels on superstructures, Pareto's statements on derivations, and the application to ideologies of Freud's theory of rationalization of motives may all be made use of to reduce radically the claims of ideologists to fight for certain commonly accepted values believed to be expressed by words and phrases such as *justice, the well-being of the people, progress*, and so on.

These "reductivistic" theories of ideologies may themselves be analyzed as ideologies. They are not conclusions reached by large-scale, patient research. On the contrary, they have been shaped as tools of ingroup conflicts.

It is a formidable task for future social research to investigate the meaning and validity of theories asserting that a conflict is not "really" about what the participants claim it is about. Today very little can be said about the outcome of such research.

The following are some hypotheses that seem to merit further testing. If two groups have conflicting economic or other fairly easily observable interests, each group can, and usually does, try to enlist neutrals to support its fight against the other group by involving objectives that it can expect the neutrals to be willing to support. Thus, if the narrow interest of power, domination, or prestige of a certain group is by this same group considered compatible with certain broader interests such as the well-being of the citizens or the dissemination of a certain religion, the group will look for arguments enabling it to describe its fight as one for these broader objectives. There is, then, a constant search for objectives that can cloak the basic ones and thereby (1) relieve ingroup members of a sense of guilt and give them a

common platform that is socially acceptable and (2) induce people to join them who do not have the basic interest in common with the ingroup.

Thus, narrow partisan interests *may* be encapsulated into impressive superstructures so that the conflicts of interests seem unimportant compared with the ideological issues at stake.

Only future research can give us methods for analyzing ideologies from this point of view, however, and let us judge the extent, if any, to which a particular ideological conflict is built up as an enormous superstructure hiding some definite basic interest of a relatively small group, compared with the total number of people involved in the conflict. Large views of political philosophy, morals, national history, etc., may be made relevant to any conflict and even pretended to motivate the campaign independently of the narrow clash of interests. That clash tends to be looked upon by the ideologists as merely a consequence of some profound schism between out- and ingroup. On the international level we might be tempted to use the conflict between the United States and Spain in 1898 as an example. The United States invoked a deep ideological reason for rescuing Cubans from the unworthy Spaniards, and Spain invoked the ideology of national honor to justify its position. A clash of power interests, however, seems to have been at the root of the conflict.

However dominant economic and related interests *may* have been in particular, perhaps in nearly all national and international conflicts, it has so far not been possible to gather sufficient relevant material to confirm hypotheses about such dominance in a fairly reliable way. There is no science of group motivation in conflicts. On the commonsense level of rough vagueness, I think one can take a stand against any one-factor theory. Causes of war have been of very different kinds. This is the conclusion of such students of war as Quincy Wright. The conclusion seems particularly tenable if we think not just of motives and causes *precipitating* war, but of factors linked by chains of motives and causes for the outbreak of wars. When we stress that the development of a *science* of these things is urgently needed, it is not so much because of the shortcomings of reasoning on the commonsense level as it is because of the misuse of professional theorizing as part of group controversy. Pseudoscientific theories such as social Darwinism have, where properly exploited, misled public opinion and will probably continue to do so until discredited by large-scale research.

One of the chief contributions of ideology research would be to show how issues in contemporary ideological conflicts are, through biased argumentation and excessive and vague unhistorical generalizations, made to appear of great moral and philosophical consequence. On the whole I venture to say that if the conflicts were divested of the superstructure of hypocritical moralizing and philosophizing, they would not be found to involve conflicts between divergent philosophies, in the sense of conflicting ultimate values or ultimate principles of knowledge. It belongs to the tasks of today's philosophers to oppose the misuse of their terminology and methods to make narrow conflicts of interests look like philosophical conflicts.

If the issues are trivialized, influences toward violence and group hostility may be reduced.¹²

These opinions on the comparative triviality of contemporary ideological conflicts from a philosophical point of view are not, and cannot be today, based on extensive research. This also holds good, of course, for any negations of the opinions. The grave danger in the present situation is that a greater and greater part of mankind is being made susceptible to ideologists speaking with certainty about problems that have not yet been attacked by reliable methods.

Dangerous Aspects of Ideologies Fostered in Schools

What about the effects of the work of ideological clarification? Will not whatever positive value it may produce be blotted out by the devastating frustrations brought about by the propagation of its results? If education continues to give us strong implicit expectations of simplicity, certainty, and permanence in means-end relations, then our answer would be yes. If we by all means of biased communication and public opinion pressure go on trying to bolster such expectations—yes.

Any training adapted to the needs and insights of our times should emphasize the risks of error and bias and the prevalence of low levels of precision in historical and social descriptions. As a contrast, look at any history textbook at nearly any page and note how fluently and convincingly causal relations are set forth, explicitly or implicitly.

Between the world wars various international institutions took up

textbook revision as part of their program. In the future such revisions should eliminate not only nationalistic exaggerations but also any form of crude violation of the principles of critical attitude. There is scarcely any field in which international understanding can be more directly and intensively served than in the preparation of textbooks.¹³ The shortcomings of most contemporary texts are so obvious that sabotage of attempts at revision cannot be easily rationalized.

A Science of Communication and of Description of Value Systems—Its Use in the Clarification of Conflicts

In ideological research, the role of communication in stirring up emotion and in the *Gleichschaltung* of public opinion cannot be studied reliably without the help of scientific tools that neutralize to some extent the bias of the social scientist himself.

It is no longer necessary for social science to make the public aware of widespread misuse of one-sided, exaggerated, and malicious descriptions of social and international problems. The role of science will be the much more difficult task of opening the public's eyes to *ingroup* misuse, that is, to the misuse by persons having approximately the same opinion and main interests as oneself in a particular conflict. As regards the outgroup, the tendency to find that its members are biased and indulge in vicious, misleading representations is all too well established. The tendency is cultivated as one of the favorite tricks of contemporary ideological discussions.

To convince ourselves by rational means that some of our own presentations of outgroup views are misleading, and that some of the outgroup's presentations of our positions are not, we must summon not only great detachment but also large amounts of scientifically analyzed observational material. Only a beginning has been made to substitute propaganda against propaganda with a discerning tool of analysis suitable for scientific studies of communication, whether outgroup or ingroup.

The task of constructing fairly neutral descriptions of ideologies faces even greater obstacles, because many people, even if they belong to different and hostile groups, have in common a fear of "objectivity," a belief that the masses are unable to take a stand if issues are not oversimplified and

made emotionally stirring. In spite of the prevailing mistrust of “vague generalities,” “evasive talk,” “big words,” and so on, there is not much eagerness among people of influence to give fairly objective versions of out-group opinions and actions.

Fundamental, Nearly Universal Norms and Attitudes Favorable to International Understanding

On the basis of psychological and sociological findings, we can very tentatively confirm the daily observation that human beings do not intentionally make each other suffer prolonged pain except in very limited kinds of situations in which they think it necessary for self-preservation, or in which they react to frustrations of such intensity that we may class them as highly abnormal. We may rely on reactions of sympathy so strong that large-scale aggression among people who are fairly satisfied as regards primary needs (food, water, shelter, sex, etc.) must be carefully organized and built up by devices such as indoctrination and isolation against contact with the antagonists. Only by such efforts can aggressive tendencies be mobilized that are sufficiently strong and widespread to counteract the reactions of sympathy.

The basic reactions of sympathy have their normative counterpart in humanitarian ethical principles believed to be valid *except* in cases in which aggression for some reason or other is conceived to be necessary. It is definitely not the other way around, viz., that aggressive principles are conceived as basic and the norms of benevolent action as exceptions to the rule.

If any particularly deep-lying influence toward international understanding should be stressed, I think it is the influence of sympathy as an immediate reaction and as a verbalized norm. Much work for international understanding can be conceived of as efforts toward removing obstacles to the free flow of sympathy reactions.

The existence of the basic reactions and norms of expansive sympathy makes it probable that all or most ideologies should show traces of them, however well concealed. In fact, this seems to be the case: though the description and propagation of political ideologies usually give predominant emphases to their aggressive and isolating elements, there are usually or always elements in them that are common to all and that recognize basic norms of benevolence.

Basic Agreements in Ideologies

A powerful but insufficiently advertised influence toward world cooperation is the far-reaching similarity of basic principles within the main political ideologies of today.¹⁴ Perhaps because of the interests in portraying outgroups as essentially different in principles of social and moral thinking, similarities have been largely ignored.

Communism, anarchism, syndicalism, and liberalism—in various forms and connotations—have in common as an ultimate, or at least as a fairly basic, aim the abolition of organized coercion implemented by brute force. Instead of the *Zwangstaat*, a society is conceived in which the members form groups voluntarily and settle disputes peacefully. In the famous wording of Engels, the state will wither away when certain grievances that now foster class antagonisms and imperialism are finally eliminated. In the various forms of anarchism, the organized and legalized use of brute force is stated to be an unconditional evil: it should be abolished if a peaceful society is to develop, with cooperation on a worldwide scale. According to various forms of liberalism, the system of free enterprise will result in such a high standard of living that everyone willing to work will have his needs satisfied, and therefore no incentives for organized violence will be found. The state should be nothing more than a polite force defending the individual's rights and liberties. No state activity would be needed to create economic security or for other economic or social purposes. Even in Nazism, such organized cruelties as genocide are conceived of as necessary evils inflicted for the purpose of a new society that does not provide for organized infliction of pain other than as part of sport activities.¹⁵

There are still groups who believe not only that some people will meet a future eternal hellfire but that they ought to endure it as a punishment. Even if it turned out that such predictions and such norms can only find acceptance because of sadistic impulses, there is no reason to believe that people other than sadists in a psychiatric sense would find conditions satisfactory in a utopia in which their enemies already had been roasted for a thousand years. Even in a Teutonic utopia like Valhalla, killing had a sportive character, as might be inferred from the resurrection each night of that day's victims. There is nothing to indicate that a person who should happen to prefer peaceful entertainment would have to take part in the

fighting. There is in the Valhalla ideology much room for violence against persons, but *on a noncoercive basis*. If wars only affected those who deliberately wanted and liked them, we should not have a “problem of wars.”

Thus, there are in contemporary and past ideologies few traces of anything like a depiction of national aggression as ultimately desirable. If organized coercion and violence are glorified, it is done largely in terms of their instrumental value for the perfection of races or societies.

The ultimate goals of political ideologies are generally very vaguely described. This is particularly the case as far as ultimate forms of society are concerned, and the vagueness and incompleteness seem to have a function similar to the corresponding character of descriptions of heaven in Christianity. Eulogistic and positive terms are used profusely; the conditions are described by words such as *joy*, *happiness*, *fulfillment*, and *perfection*. There is no exploitation, no coercion, no violence, no poverty, no selfish motives, no need for exploitation, and so on.

The steps to be taken to realize the utopian (the future, imagined states of) society are also left vague and incomplete *except insofar as first steps go*. These steps, which largely have a character of means rather than ends, are described in concrete terms, and the hypotheses of their success are—as mentioned in previous sections—given excessive credence. It is on the basis of such first steps that different ideologies are judged incompatible: ideological controversies are largely made up of mutual denunciations of immediate programs, as well as of mutual defamations of the sincerity of proclamations on further aims, including ultimate ones.

The proportionality between vagueness and level of aims in the means-end hierarchies may in part be explained by the prevalence of rather narrow and immediate aims among those who try to shape ideologies to suit their group interests.

However important for any long-range peace effort, the similarity and compatibility of ultimate goals as pictured in ideologies does not in itself give us important clues for the reduction of current major tensions. The insistence of the leaders of ideological groups that those in the opposing camps have radically different ultimate aims is a minor effect of those tensions rather than a cause. If research can be centered on the function of ideologies to mislead great numbers of people to work for the selfish interests of narrow groups, the vitality of an important source of organized aggres-

sion may be reduced. This would, first of all, imply detailed analysis of the means-end beliefs to clarify their highly hypothetical character, and second, imply a comparison of ends without distorting the contentions of out-groups.

Such research cannot, however, directly reduce the clashes of interests of the groups that use ideologies to mobilize peoples and institutions on their side. Neither can it reduce the aggressions rooted in unsatisfactory living conditions. The aim of reducing national aggression and increasing international understanding brings us into a larger sphere of problems than that tackled by ideological research as emphasized in this article. It brings us into economics, sociology, psychology, and history, where influential factors can be tentatively identified. The discussion of such factors lies outside the scope of this contribution. Some words will be said, however, about the interconnection among various factors.

Causal Weight of Factors Influencing National Aggression

Time and energy are easily wasted in discussions of the relative importance of various influences on national aggression. It should be borne in mind that what can be expected from social scientists is primarily hypotheses about certain interactions of factors under postulated conditions that are very difficult to compare with "actual conditions" in the world at a particular moment.¹⁶ Thus, under some conditions increases in mutual sympathy and understanding and in economic security and equality may be factors interacting with others so as to precipitate war. Churchill, among others, seems to mean that under the particular conditions in Europe between the two world wars, pacific temper, benevolence, and economic security influenced England and France, especially through leaders such as Neville Chamberlain, to adopt a policy by which a great war was precipitated in 1939 instead of no war breaking out at all or only a small one in 1935, 1936, or 1938.

The expressions *on the average* and *on the whole*, as used in this survey in statements about the way in which factor *x* influences national aggression, have no place in more exacting descriptions. We are in possession of, or we can get, immensely more information on factors operating under rather narrowly and precisely delimited sets of conditions. It is on the basis of ten-

tative hypotheses about the frequency of such sets of conditions and about their similarity to those prevailing at any moment that we should determine which factors should be deliberately strengthened by individual and group action.

In this connection, I should like to stress yet another methodological difficulty in the evaluation of answers to questions about influences on national aggression: Churchill's insistence on the causal role of pacifism and goodwill in the development of World War II—rather than, for example, militarism in Germany—probably owes to his belief that the policy of Great Britain might in 1935–1939 “easily” have been otherwise; if men sharing Churchill's convictions had been in power, there would have been no war. Thus, Churchill labels World War II “the unnecessary war.” In general, answers to questions about influences on national aggression are, however contradictory they may look, rather complementary or mutually independent, because the criteria for calling factors “causes” of or “influences” on national aggression include, in practice at least, criteria such as the following: (1) Human beings might have given events another course by eliminating or changing factor *x*. Thus, the likelihood that we could have changed certain features makes us picture those features as preeminently important. (2) If a factor is conspicuous and easily observed, it is counted as causally more important than if it is inconspicuous. The stage of industrial development, or more generally, the stage of the means of production, is considered extremely important in the history of civilization, partly because it is so easily observable. Any particular set of conditions precipitating a change in industrial development might in theory be considered just as important, but such conditions are often left unmentioned because they are more complex and more difficult to observe and describe. Such conditions would include the state of science, the organization of scientific and administrative work, the intelligence and emotional states of scientists, the stability of the economic and social status of the workers making the tools, and so on.

Against this “relativism” in our attitude to the hypotheses of degrees of influence, it might be objected that it would undermine the now fairly well established maxim “There is no biological basis of war.” That maxim, however, is only a vague popularization of well-established hypotheses of the following kind: “there are no biological factors that persistently influ-

ence national aggression, however economic, social, and psychological conditions are altered.”*^{17,18}

*In signing the *joint statement* I have subscribed to some very general—and necessarily rather vague—statements on the subjects of the present inquiry. Paragraphs E, F, H, and the last part of C deal with issues discussed in the preceding pages in terms of ideological conflicts. In the light of what I have said on the relativity of causal weighting, it would be misleading to speak of economic or psychological or any other particular class of factors as the “real” or “main” influences on national aggression. I should maintain, however, that an organized battle against certain fairly general features of ideologies, such as their claims on finality and certainty and their more or less deliberate vagueness, ambiguity, and distorted outgroup descriptions, may result in a sort of mental disarmament that makes appeals to large-scale aggression less effective than they have been so far.

A Plea for Pluralism in Philosophy and Physics

The impact of science on society and on the individual is today of such an order that any view or vision of the world and humankind labeled unscientific by authoritative scientists or philosophers of science has little chance of being enjoyed, expressed, or made an object of serious logical and empirical research. Among such worldviews, too easily ignored by admirers and philosophers of science, I have particularly in mind those conventionally classed as not empirical or not rational, including a list of philosophies inspired by the Dane Søren Kierkegaard and by the Germans Georg Hegel and Karl Marx, but I also have artistic visions in mind, such as those of the best science fiction.

To people with different visions, one and the same scientific result means something different. They agree completely on an “object level” but may disagree completely on the “metalevels.” The differences might be part of the domain for serious metascientific research, but little has been done so far. It is a great task to help verbalize and conceptualize such visions so that others can see human beings, the universe, and world history with the coloring specific to a particular vision. Without deep engagement and serious research, we tend toward eclecticism, traditionalism, incongruence, “grayness,” and incompleteness (partiality) in our views.

My plea for a multiplicity of precisely formulated views in the philosophy of science is not an invitation to physicists to engage in vague specula-

This article was reprinted with permission from *Physics, Logic, and History. Based on the First International Colloquium held at the University of Denver, May 16–20, 1966*, edited by Wolfgang Yourgrau and Allen D. Breck (New York: Plenum Press, 1970), 129–46.

tion or to take seriously what this or that philosopher—for example, Marx, Hegel, or Kierkegaard—has said about science or what he has intended to be answers to scientific problems. It is first a plea for extreme vigilance in distinguishing intersubjective, intercultural results of physical research proper from interpretations of those results within a framework larger than professional, technical, physical science. Second, it is a plea that all different, mutually inconsistent interpretations such as are suggested—but practically never more than suggested—by competent physicists and philosophers of physics be elaborated with painful clearness and in detail. An opposite plea would be for an immediate decision about what is true and what is false when one uses, for example, traditional, vague formulations of so-called operationalism, pragmatism, rationalism, dialectical materialism, idealism, and so on.

The world of personalities, of consistent personal perspective, is today still a colorful world, immensely satisfying to contemplate in its unbelievable variety. It would be disastrous to use the prestige of science to lay down limits and exclude some worldviews not refuted by science, or to call them irrational or intellectually dishonest because they are inconsistent with a definite “correct” philosophy of science proclaimed to be the only valid one. The same holds for metascientific views considered testable but not yet tested by genuine interpersonal and intercultural methods.

After all, the carefully formulated *results* of genuine scientific research are largely neutral toward differences in worldviews as long as these concern fundamentals: there is always room for differences in ultimate rules, valuations, premises, and postulates. As long as we do not have any established criterion for testing different metascientific theories concerning the completeness of a theory (for example, quantum mechanics), why not work out different views of completeness in all preciseness and detail instead of trying to promote just one view that is not even stated clearly?

Let me sum up what I wish to communicate so far: Comparability of worldviews requires precise formulation. Precisely formulated, basic positions are mostly seen to involve different assumptions and postulates. Attempts to point out the “true,” “correct,” or “valid” are futile in such cases. Pseudorefutations promote conformity, leaving us with colorless world pictures devoid of inspiration from visions.

Now let us offer some words about the use of the term *fundamental*, or

basic. The degree of fundamentality of a position is relative to the status of the discussion and research at any given moment. Roughly, those propositions, rules, or norms are ultimate that make up the last links in argumentations. If mathematics, as suggested by Lakatos, has no foundations outside itself, certain purely mathematical propositions and rules will be fundamental to any comprehensive position within mathematics. Philosophy of mathematics will then take over, however, asking, *Why* does not mathematics have any foundation outside itself? If the answer is considered a satisfying one, the questioner comes to a rest. There are questions, though, that lead us farther, namely: What is a satisfactory explanation? Which are the criteria of a true or good explanation, and are there ways of testing its truth or goodness? Now we certainly are outside physics, mathematics, or history, and our argumentations lead us to take up positions that I would call ultimate, basic, or fundamental—without in any way implying that there is any eternal or absolute resting point in questioning.

The tolerant and liberal attitude in philosophy of science serves the interest of keeping alive and working out in detail views that as yet cannot be intersubjectively and decisively tested.

Let T_1 and T_2 be different theories of explanation, with both descriptive and prescriptive components. What would constitute tolerance and liberalism in relation to them? If P is a researcher in the field of metatheory and he has a conceptual frame of reference in which he can state, compare, and test the truth or validity of T_1 and T_2 , considerations of tolerance and liberalism do not enter the picture in any way other than they would if he were dealing with two theories, for example, theories about the relation between molecular weight and the boiling point of alcohols, or any other particular scientific domain.

If T_1 and T_2 are not very superficial, however, they are likely to reach conceptual layers for which we, today, do not have proper intersubjective and intercultural methods of testing. This holds especially for the prescriptive component. The metascientific researcher is apt to succumb to illusions of comparability and close the door to research, insisting that he has performed a test with decisive results in favor of T_1 (or T_2).

Among the scientifically incomparable theories of explanation it is enough here to mention those tending toward seeing a *reduction* of the

thing explained (the explanandum) to the explanans, and those tending toward seeing a mere *shorthand description* of observational results.

Let, then, T_1 and T_2 be two different theories of testing, confirming, disconfirming, corroborating, and related activities. As they appear today, they have both descriptive and prescriptive features. There are at present no acknowledged intersubjective and intercultural ways of testing theories of testing. If P_1 believes in T_1 , he will normally use it to test T_2 , in spite of T_2 containing rules or descriptions in conflict with T_1 ; and P_2 will do the same with T_1 . This circularity of procedure is, in some cases, inevitable, and perhaps only extreme rationalists will find the situation repugnant. It is at least clear, though, that metatheories of testing are not today scientifically testable.

In fields in which convictions are strong and research is weak, tolerance means adhering to intellectually decent ways of debate: not to pretend to disprove a theory without having bothered to state it clearly; not to pretend to have refuted a theory or point of view when one has allowed oneself to take for granted certain premises, presuppositions, or postulates that are negated in that theory or point of view.

What is most needed in these fields is an intense fight for explicitness. Only if certain levels of explicitness are reached can a serious search for methods of comparison and testing be instigated. Only then can truth or falsity be discerned—if ever.

Research attitude here involves cooperation between different schools of thought to help make each other's point of view clearer. It is often easier for researcher P_1 adhering to T_1 to explicate a hidden assumption in the rival theory T_2 than it is for P_2 , who himself has worked for years with T_2 and believes in T_2 .

Hertz, Poincaré, Duhem, Planck, Einstein, and Bohr, to mention only a few outstanding names in the realm of philosophy of science, had different overall pictures of science, of its basic conceptual framework and its methodology. The differences are parts of differences in total views, made more or less explicit in their nonscientific writings and sayings.

Any effort to restrict the variety of such total views by pretending that some are "unscientific" is not only unempirical, but goes against the kind of intellectual honesty and open-mindedness that is the greatest gift of research to human beings.

If two positions cannot be compared as to truth, if they cannot be refuted in the sense of Popper, the one does not, in relation to available conceptual frameworks, have a greater validity than the other. Neither can we say that both are lacking in validity, because that would leave us without anything to start out with. I propose putting it as follows:

All noncontradictory, fundamental positions (points of view) have the same non-zero status of validity.

Open-minded, constructive research, having such positions as an object, consists of clarifying and increasing the scope of them rather than trying to reduce their number. Reduction in number does not occur just by pointing out inconsistencies. This is indeed sometimes difficult, because concepts of consistency show variation with variation of position. It is also difficult because pointing out inconsistency requires a semantics, and today we do not have one, single semantic system but various incomplete, competing ones.

The term *validity* needs (even in this preliminary discussion) some elucidation. Truth—as agreement with reality—is here taken to be *a kind of* validity. The kind of validity of a fundamental position is not truth; it belongs to the class of validities such that p and non- p may both be valid, though p may not be both valid and not valid.

The logic of this concept of validity is closely related to that of tenability: a view is tenable if not refuted. If neither p nor non- p is refuted, they are *both* tenable, but, of course, not within one unit of argumentation. The term *refuted* as used here does, of course, need some elucidation, but I am afraid I must stop here.

The use of the term *reality* in philosophy of science (for example, as accepted by Mercier) immediately suggests questions about the criteria of being real and the various positions concerning reality and appearance—going all the way back to the dialogues of Plato. Most of our discussions in philosophy of science certainly need not, even *should* not, go that far. My plea for pluralism is—in respect to the debate on concepts and criteria of reality and appearance—the modest one of proposing that no door leading to the various ultimate positions should be shut by restrictive clauses.

The trend today is unfortunately against pluralism, because it is more and more plain that Eddington, Heisenberg, Rosenfeld, and others have

misled many physicists and made them adopt strange, philosophically interesting but unphysical views. However, a cry of “back to normality” or “back to realism” will not, I feel confident, close the door to new approaches, even if we agree with Landé that to maintain that the electron has *no* position between two measurements is rhetoric rather than a revolution in the theory of knowledge. The antipluralist trend is sound as a reaction against pluralism “by invasion”—by invading “physics itself” and constructing unnecessary and strange philosophical interpretations within this very discipline. (But what is “physics itself”?)

It is part of the historian’s business to try to make us experience from the inside (by *Einfühlung*) extremely different views of man and the universe. How is this possible? It seems to rest upon the assumption that the reader of a historical or philosophical work portraying the differences has a conceptual framework wide enough to cover the most extreme differences. If this were the case, we are in a sense back to monism, since a universal conceptual framework would be the only ultimate or basic one. I shall argue that we need not assume we have such an ultimate *conceptual* framework in order to make pluralism understandable and defensible at a nontechnical level. I need for this argumentation to introduce some semantic concepts.

If somebody utters a sentence T_0 with truth—or validity—claim, the definiteness (not necessarily the “depth”) of cognitive meaning is limited by the set of discriminations he makes. The network of discriminations in the form of distinctions in meaning is not a stable one. Thus, if I say that such and such a ship weighs ten thousand *tons* or that π and h (Planck) are *constants*, I may have a very crude idea of what I intend to say, but it may be definite enough *for the purpose at hand*. An expert at Lloyd’s Register of Shipping, for example, will, in his professional capacity, have a high or sharp definiteness of intention. It can be conveyed to outsiders only by means of perhaps five hundred words. As regards the term *constant*, one’s network or grading of discriminations may be at least temporarily refined by reading articles such as those of Yourgrau about different usages of the term *constant*, or by trying to compete with Quine, Church, or Mates in introducing the term *constant* in mathematical logic, or by trying to prove some fairly general theorems about constants. Degrees of definiteness of intention may be, and have been, experimentally measured and compared, but this is a complicated affair.

Economy of thought requires that we work with a definiteness of intention commensurate with the requirements of the task, of the problems confronting us at the time. Problems in quantum physics confronting physicists who do not aim at making radical advances, do not require a high definiteness of intention regarding the significance of the symbols in, let us say, the Heisenberg equations. It is, therefore, misleading to say, as many do, that most physicists subscribe to the Copenhagen interpretation. Insofar as the so-called Copenhagen interpretation is formulated as a *specific* interpretation, contrasted with others, only a small fraction of researchers and teachers in physics in Western countries seem to discriminate. A high percentage at least *say* they do not discriminate. Their definiteness of intention is too low to reach relevant distinctions.

So much about the concept of definiteness of intention. The other concept, preciseness, can be introduced as follows: a sentence T_1 is more precise than a sentence T_0 if there is at least one interpretation to which T_0 admits but T_1 does not, and there is no interpretation admitted by T_1 that is not also admitted by T_0 .

If T_0 and T_1 are sentences in the philosophy of science, an interesting criterion of admittance is the actual ways of interpreting T_0 and T_1 within a competency group defined, for example, by having training in both physical and philosophical research.

Thus, when Leon Rosenfeld says to an audience of philosophers of science, "The type of causality of classical physics is determinism," the level of preciseness in communication will be measured roughly by mapping out the diversity of interpretations among the audience at hand. This level will be dependent, but of course not entirely dependent, on the diversity of interpretations of the terms *causality*, *classical physics*, and *determinism*.

That T_1 is more precise than T_0 may also be defined by saying that the range of differences in interpretation of T_1 falls within the range of interpretation of T_0 , or that the range of interpretation of T_1 is a subclass of interpretations of T_0 .

Applying these concepts to the pluralist postulate, I suggest that we place any *talking about* wide systems, the metasystematic utterances, at a T_0 level. It is a relatively neutral level, not because of wideness of scope or vastness or abstractness of conceptions, but because of its low level of discriminations (in relation to systematic conceptualizations). Any suffi-

ciently vigorous effort to exact a delimitation of the pluralism postulate inevitably plunges it into the arms of a definite system or family of systems.

This is easily seen, considering the fact that the above formulation of pluralism includes the words *noncontradictory*, *fundamental*, *position*, and *validity*. Any fairly precise account of what might be intended by these vague and ambiguous words must reveal some worldview idiosyncrasies of the author, or some of his basic methodological positions. This ruins the communicability of the pluralism, making it understandable only within a definite camp. Pluralism is, therefore, in some sense only an ad hoc and rough position, “exposed to wind and weather” and awaiting its destruction—but what is not ad hoc?

Pluralism does not *rule out* that ultimately there must be one truth. Except, however, in matters of little concern, or in practical affairs, many of us are never able to satisfy ourselves for any reasonable length of time with any definite solution to even one major theoretical question. Why not let this color one’s stand toward ultimate positions?

Let me make a digression on the plurality of “embryonic” worldviews among nonphilosophers.

It is almost universally believed among philosophers that nonphilosophers (or more specifically, men of common sense and, of course, youngsters who have not yet heard of philosophy) are naive realists in ontology, that they think truth consists in agreement with reality, and so on. If we take *naive realism*, *ontology*, *truth*, and *agreement with reality* as vague and ambiguous words on the T_0 level, they can be used as starting points of preciseness that lead us ultimately to interesting differences in worldviews in general, and metascientific views in particular.

If empirical evidence is considered of any importance in this field of easy speculation, it supports an opposite conclusion. When they are directly or indirectly stimulated toward formulating philosophical opinions, I have found that fourteen- to eighteen-year-olds express in a crude way, with low definiteness of intention, very different ontologies, epistemologies, and other positions of fundamental import.

In environments in which certain trends of philosophy dominate, gifted young students tend to adopt the current opinions and attitudes, although an impressive teacher may induce some of the students to accept his views even if they are looked down upon within the dominating circle.

This is the exception, however. In any case, the narrowing down of variation is not attributable to any intellectual inferiority of certain basic views, and certainly not to clear-cut falsification. Intellectually, there seems to be a decline in variation owing to absence of systematic development of various intensively incompatible views on the professional level (the “monolithic” tendency). The “amateurs,” kept isolated from authoritarian adults, show a far greater tolerance of ambiguity (as this term is used in psychology), and also the courage to leave debates on fundamentals open. These are, of course, empirical hypotheses, and they have only in part been subjected to research. Results so far obtained point in that direction, however.

Finally, what is the relation of philosophical pluralism to the contemporary discussion of physical reality? Listening to what some physicists authoritatively tell us, pluralists get into trouble: to accept as pure physics what they tell us *must* today be accepted—and not as conceptions derived from some basic conceptions—entails accepting certain fundamental positions as the only possible ones. Thus, Leon Rosenfeld *insists* that the development of physics entails certain views in the logic of concepts. If this logic (which is more akin to ontology in the usual sense) is expanded, it fits Hegelian basic positions, not others. Those of us who are not physicists are accustomed, and inclined, to accept at face value what we are told is pure physics, and we are tempted to look at certain philosophies as falsified by physics. This means giving up pluralism. Listening to other physicists, however, we begin to suspect that physicists have succumbed to a gigantic non sequitur and are offering us positions on false grounds. Hence, we shall look with interest for evidence that different groups of contemporary physicists, all presumably very competent, have incorporated different positions in their so-called physics. This is happily the case. We should, therefore, be in a position to discriminate “pure physics” from “philosophical physics,” looking for pure physics in what is agreed upon by all physicists today. Philosophical physics would be physics explicitly developed within the frame of reference of a fundamental position.

Pure, unphilosophical physics is, of course, strictly speaking, nonexistent; it is a fiction. However, a position akin to Pierre Duhem’s may well be developed—*akin* to Duhem’s, because his doctrine that the succession of good physical theories makes them approximate a natural classification of real objects cannot, if accepted at face value, avoid coloring the physicist’s

criterion of a good theory. This makes him take a kind of realist philosophical position, thus *leaving* his “pure” physics.

The pluralist in me is interested in the further elaboration and clarification of the subjectivist interpretation worked out by Heisenberg. Eddington can be radicalized in the direction of Berkeley’s idealism. Of value to pluralism, too, is the idea of Leon Rosenfeld and others that there is something dialectical, in the Hegelian or Marxian sense, in the doctrine of complementarity. In his famous Tokyo lecture (1960) this eminent, vehemently antipluralist physicist, Rosenfeld, made quantum physics part of a far from trivial metaphysics. He there said, among other things, that “Complementarity denotes the logical relation, of quite a new type, between concepts which *are mutually exclusive*, and which therefore cannot be considered at the same time because that would lead to logical mistakes, but which, nevertheless, must both be used in order to give a complete description of the situation.” Logicians have not, as far as I know, been inspired to work on this quite new type of logical relation. The main reason, I think, is that the environment of logicians (in the West) is un-Hegelian or even anti-Hegelian: the notions of “concept” and of “logic” implicit in Rosenfeld’s views do not belong within the mainstream of formal logic; they do belong to the Hegelian framework of Rosenfeld’s philosophical physics.

Neither the Heisenberg nor the Rosenfeld philosophical theory has as yet the preciseness required for univocal location within the network of fundamental positions, but I hope that some philosophically trained Copenhagen people will take up the problem of how to find careful, precise formulations. This will not, however, be of any consequence if Landé is right: the point of departure *inside physics* of the Heisenberg and the Rosenfeld theory does not at all warrant any interpretations different from older particle physics. A quantum physics without particle-wave dualism cuts out any special quantum philosophy of the Heisenberg and Rosenfeld varieties.

What has the development of physics in the last decades to do with philosophical pluralism? The developments have convinced me, first, that fundamental advances in physics are made by physicists for whom physics is not a formidable set of tricks of the trade, but whose thinking proceeds within the framework of ultimate positions, of philosophical interpretations of the terms and formulas used in physics. With time, the philosophical theory of these physicists is “rubbed off,” because physical practice does

not require preciseness in fundamentals. Second, I am convinced that the positions among creative physicists are and will continue to be mutually inconsistent, that efforts to stifle the sources of diverse philosophical inspiration constitute not only a methodological but a general cultural evil. The fight between supporters of so-called idealist and realist conceptions is barren except for increasing the explicitness, comprehensiveness, and consistency of each kind of conception.

The pluralist Bernard d'Espagnat says in his carefully written *Conceptions de la physique contemporaine* (1965: 11) that there are as many original interpretations of physics as there are "possible conceptions of the relation between man and the world." This is a happy formulation, I think, if we are permitted to add "basic" to his term "relation between man and the world," and "at least" before "as many." In the matter of particulars, or nonbasic problems, most views (even among the consistent ones) are eliminated by research, or will soon be eliminated as improbable, badly corroborated, and so on. Pluralism based on keeping alive refuted hypotheses is, of course, uninteresting to us as researchers.

Let me append to this pro-pluralist sermon a remark that might (mistakenly) be taken as antipluralist: Vigier embraced the idea of a theory of hidden variables before he could describe a single possibility of experimental confirmation. He has been unjustifiably criticized for this among some physicists, but, on behalf of all pluralist philosophers of the world, I would thank him; we have, as philosophers, little or no chance at all of creating alternatives in physics and are, thus, rather helpless when physicists point to certain interpretations as inevitable and definitive. Courageous physicists who suggest new paths even before it is seen where (or what) they might lead to experimentally are, therefore, especially welcomed. Vigier was inspired, however, by a form of dialectical materialism, in a way that would scarcely be possible if he were a pluralist in philosophy. This underlines the curious fact that it is difficult simultaneously to promote unconditionally both pluralism and swift, radical advancement in science.¹

Discussion

Wolfgang Yourgrau: Naess seems to plead for some sort of tremendous tolerance and liberalism, as far as philosophical schools are concerned. He is say-

ing, it seems to me, that all philosophical schools are more or less equivalent. According to my opinion, they can't all be valid. Having the sheep with the lions, the existentialists and the analytical philosophers, the rationalists and the realists, the pragmatists and the metaphysicians, all in one happy paradise—I don't believe in the probability of such a paradise.

In fact, it can be proved that some views held by a given philosophical school are in no way consistent with other views. So why not draw the most plausible conclusions? If they are wrong, we make corrections by trial and error. Philosophy, physics, mathematics—they all have learned from errors. You can't afford the luxury of having no viewpoint at all and simply say, "Well, I listen to you and you listen to me." Philosophically I find such an attitude slightly . . . repulsive.

In mathematics we have three famous schools. I grant that this *is* pluralism in a way, but even though one may contend that the intuitionists or the logicians or the formalists have each a very good case, one still has to say, "I am either a formalist or an intuitionist or a logicist." I don't think one can be creative in three *generically* different scores like a gifted musician.

When it comes to logic, although I have heard about many "logics," I think it has been very beautifully shown by Quine and later by other thinkers that most findings of modal logic can be reduced to nonmodal logic. These are interesting adventures, but on the whole I think we have a definitely unique viewpoint even among logicians, although one may pay tribute, or at least lip service, to other logicians with whom one doesn't agree.

I would like to stress that (although I agree the limits of definiteness are not very sharp) our aim must be, as scholars, to sharpen our concepts *even at the risk of antagonizing our colleagues*. There are situations in which one just cannot build bridges even within his own field. Bridges to another discipline are one thing; illusory bridges among your own fraternity are an entirely different thing.

Naess's viewpoint on contemporary physics is interesting, but unfortunately I can't agree with it. For me, any sincere physicist with academic integrity tries to tell us something about the world, sometimes in very involved conceptual language, sometimes using a mathematical apparatus that is intricate and abstract. But still, he is for me only a physicist and not a mathematician if he really wants to know something about reality. And

there I think pluralism is an approach I would not recommend to my students as *the* ideal recipe.

Finally, Vigier is responsible, together with Bohm et al., for a very interesting new model of the elementary particle and an aesthetically fascinating theory. Regrettably, as long as I haven't been shown for his precious model and theory even an iota of experimental evidence, I have to consider the adherents to those "original" ideas as quixotic. But let me confess that the very moment when I see an ever so slight experiential support for Vigier's contentions (and those of his collaborators), I shall become converted and eschew all my previous commitments in that particular domain.

Arne Naess: Let me restate the definition of the term *pluralism* as I used it. All explicit noncontradictory, fundamental positions have the same non-zero argumentational status of validity. Explicitness and fundamentality require preciseness. This rules out the standard statements of philosophical schools, as far as I can see. Behind the vague slogans of schools, however, are differences of basic views. These should be explicated.

At the lowest level of preciseness, the T_0 level, contradictions do not appear, nor are interesting differences in premises, postulates, and rules of inference statable. To be able correctly to say to somebody, "You stated a contradiction," is a compliment because it means he operates above a certain minimum level of preciseness, and this is what I, of course, will require of an explicit, fundamental position. If we cannot locate where you stand in the landscape, how can we argue with you?

I am not excessively liberal and tolerant toward so-called schools of philosophy as we find them "defined" in dictionaries and bad histories of philosophy. What is asked for is not "tremendous tolerance and liberalism," but rather abstinence from totalitarian, sectarian, and conformist attitudes, and willingness to take part in teamwork involving serious research across ideological boundaries.

It would, of course, be queer to proclaim that "all philosophical schools are more or less equivalent" and their premises, assumptions, presuppositions, and postulates all "valid." Most school formulations are not precise enough even to make exact comparisons or to search for inconsistencies. Mists do not collide—and note: physicists are responsible for a lot of this mist!

Researchers do not like to be labeled by names of so-called schools, and this also holds for philosophers. A formulation said to express an assertion or rule characteristic of pragmatism *as a school* is mostly a formulation nobody would accept or take seriously, because of vagueness and ambiguity. The same is true for formulations pretending somehow to catch the essence of, for example, "existentialism," "Hegelianism," "ordinary-language philosophy," or "rationalism." When Yourgrau states that "all philosophical schools" cannot be "valid," he may have ism formulations in mind, and I agree. *Validity* and *invalidity* are terms we both would reserve for formulations of statements or rules that show a minimum level of interpersonal preciseness. I have only such formulations in mind when advocating pluralism.

If, on the other hand, we take carefully selected formulations from, for example, the so-called pragmatist C. I. Lewis or Quine or from the anti-pragmatist Gottlob Frege, or from a Hegelian like Grenness, some may have the character of fundamentality that makes them "equivalid," "acceptable one at a time." That is, there is no sufficiently wide conceptual framework, including semantics and methodology, within which they can be scientifically compared and tested. Maybe future generations will see such frameworks; today, it seems best to travel on different roads. To invoke trial and error as a test method here would be naive.

The current philosophy of physics includes a great number of metascientific sentences on "completeness of a theory," "explanation," "observation," "levels of physical reality," "interaction of subject and object," "path of a particle." What is needed more than anything else is more precise and elaborate formulation of the positions suggested but not clarified by those sentences. Cooperation among people trained in philosophy and physics is needed to make use of the suggestions of Heisenberg, Rosenfeld, Bohr, Fock, Bohm, Vigier, Landé, Weiszäcker, de Broglie, and others. The school terms *idealism*, *pragmatism*, *dialectical materialism*, and so on, are apt to thicken rather than dispel the haze. Moreover, the stress on one position being true and the other false is premature; it leads away from constructive meta-research and the difficult work of finding hidden premises and of formulating, as exactly as possible, differences in postulates, fundamental assumptions, and styles of research. Contrasting positions must be sharpened, kept alive until, if possible, refuted in an intellectually honest way.

The emphasis on multiplicity of mutually inconsistent views is *not* eclecticism. The eclectic is rather a monist than a pluralist, rather an irrationalist in the “Popperian” sense² than a rationalist.

Jean-Pierre Vigiér: I wholeheartedly agree with Yourgrau. I think the real problems now, which are philosophical problems, are being fought on quite a different battlefield: the battlefield of science. The great periods of philosophy were precisely the periods in which the problems were tied to an explosion of scientific knowledge such as in Greece, the Renaissance, etc. Now in a sense we live in a similar but even more exciting period. Progress in the last forty years has been more important than in the last two thousand years; nine out of ten scientists who have ever lived are alive at present.

If one reflects on the nature of the big problems to which our knowledge has been brought to bear in the last ten years, we see we are on the way to answering problems that have been discussed on a purely rhetorical level for the last two thousand years between, for instance, the materialists and the idealists.

Consider, for example, the problem of whether life can be explained in terms of a possible behavior of matter. The answer to that problem is being given now, not by philosophers but by the scientists themselves. It rests on the discovery of DNA and the introduction of the feedback ideas of Wiener and many other scientists into the theory of life. This is the beginning of a real definition of the problem of life.

There is the same thing in the problems of soul and consciousness. Thinking machines are beginning to clarify certain elements of what “thought” is. This means that the corresponding problems are moved from the level of words to the level of the laboratory. I think the whole issue, of course, is that of synthesis within scientific knowledge.

I am against eclecticism. All ideas should be allowed to be expressed, but in science they are fought and settled on a very special level, that of scientific practice, by the results of experiments. I don’t think the discussion with the Copenhagen school is a merely rhetorical one. I am certain it is an issue that is going to be settled on the scientific level. A lot of so-called philosophy appears to me to be just sophistry. People like Teilhard de Chardin pretend to answer questions that they have no right to answer because all this talk about spheres is just words. The people who are doing the

actual work are the biologists, for they are really approaching, on a precise, controllable level, the fundamental problems raised by our knowledge. Hence, questions concerning physics or the laws of physics should be settled by the physicists themselves on the level of experiment. I want to chase the ideologists away from knowledge because the truly fundamental revolution of our time is precisely the construction of a synthesis out of scientific knowledge.

Now, this does not mean that I think there is a unique philosophy that is going to issue forth from the discoveries of scientific knowledge. I hold that we will observe in the following years new scientific revolutions—this is not a Teilhard de Chardin-like prediction—and a new qualitative synthesis will arise because science works by successive revolutions. There are long periods of accumulation of knowledge and then periods of breakthrough that change the whole traditional point of view.

If one reflects on the nature of modern science, one sees that all the barriers between the different branches of knowledge are falling down. Consider, for example, the impact of the work of a man like Norbert Wiener. I think that Wiener's contribution will appear, in time, as important perhaps as that of Descartes. The ideas of cybernetics, the notion of feedback, have transformed completely our ideas about the behavior of nature and about causality. They have opened the way to a new scientific explanation of what is life and what is soul.

What is really happening is the explosion of science. Now, instead of having long periods in which different branches of knowledge were independently deadlocked, any revolution in one branch changes the outlook in all other branches.

This is a fantastic change and explosion, and of course it is imperative to bring scientists and philosophers together. But, as I say, I have a deep conviction that the most advanced thought, the solution of the most advanced problems, originates in the laboratories themselves.

H. J. Treder: I think one of the best remarks Einstein has made about philosophical problems is that all physicists are philosophical opportunists. They do not have a philosophical system that will work. A physicist might be in one respect a realist and in another a positivist. The conceptions of the philosophers are only working instruments for the physicists. Of course,

some physicists may or may not lean toward some special philosophical systems. A relevant criterion of the physical meaning of the works of these physicists is the invariance of their results according to different philosophical points of view.

Naess: Since I was trained in psychology in general and social psychology in particular, the interview technique is natural to me; so I asked physicists doing research in quantum physics whether they apply such a method to the Copenhagen or any other interpretation. The answers mostly amounted to a denial that they have had to take a stand. Their work is neutral toward crucial differences of interpretation, and they often succeed, as they admit, by “mere” tricks of the trade. Further, if their work happens to put them in close contact with burning questions of metascience and of fundamental views in general, they often are, or act as, “opportunists,” as pointed out by Treder. In other, perhaps rarer, cases, physicists do not act in this way, as exemplified by Niels Bohr and Einstein, for whom there was no clear distinction between a scientifically “pure” physics and a physics interpreted within a broader framework of metascientific and fundamental issues. In the early 1920s, so-called pragmatist and positivist attitudes were perhaps the *most* opportune ideas for “getting quantum physics moving.” Einstein could not leave his fundamental positions, however, and Heisenberg did one of the crucial jobs. (“What is a physical theory?” and “What is physical reality?” were burning questions affecting their conceptions *in* as well as *about* physics.) In still other cases, metascientific issues *dominate* the physicist in his work, as was the case with Pierre Duhem. The result was sometimes a happy one, sometimes a deplorable one, from the point of view of heuristics.

All this I try to elucidate by using my concept of “depth of intention.” The varieties of fundamental positions arise from a great depth of intention in any extraordinary situation. For most researchers in most of their work, great depth and the corresponding fine-grained set of discriminations (to use a phrase from psychophysics) are a luxury.

Recent significant advances in molecular biology have brought to the fore just those problems that cannot be solved in the laboratory alone, but that require going back to premises, postulates, and basic human policies. The “social” sciences in their turn require us to pose as precisely as possible

the values we shall defend. They do not operate automatically but require "input." When ordinary people ask scientists to state the implications of the discovery of DNA, to show what questions of eugenics, ethics, politics are implied, an answer must be stated in ordinary language, not in that of the biological laboratory. The scientist must be conscious of his own position in the vast metascientific field of rational debate.

Hermann Bondi: On the historical side, I think Naess's remark about great advances in physics coming from physicists with a philosophical bent of mind is true in some cases and untrue in others. The greatest experimental physicist of our century, Rutherford, was perhaps the most nonphilosophical thinker who ever lived. Dirac made many great contributions, but I think what most would regard as his greatest, viz., the equations of relativistic quantum mechanics, were essentially a trick of the trade, a usable one, but no more than that. So I cannot entirely agree there.

On the other hand, when Naess pleads for pluralism, then it seems to me very clear that pluralism is of the very essence of science. To me, it is the greatest glory of science that people of different religions and different ideologies can work together effectively. It shows that in science there are certain methods on which we can agree, in which experiment forces agreement, even if there are others on which we do not agree.

Next, there is the point at which I am perhaps a little more "Vigierist" than Vigier himself. There is science, yes, and in this we have theories that are testable in the "Popperian" sense. But we do not know (until we have explored alternatives) which part of the framework is essential and which is not. For eighty years after Maxwell proposed his theory, the field concept was thought to be a vital part of it, and the tests of electromagnetic theories were thought to show that the field concept was right. Then Wheeler and Feynman demonstrated that we could arrive at Maxwell's equations from an "action at a distance" concept, leading to the same experimental tests, and so we now know that the field concept is only *one* alternative basis. It has made the field part of the Maxwell theory move out of science just because it is no longer testable. But removing it from science strengthens the demarcation and is thus a true scientific contribution. If the Bohm-Vigier theory does not lead to any possible experimental discrimination, it will yet show that different approaches are possible. Thereby, it will have removed from science part of the usual foundations of

quantum theory as not being testable. Therefore, it will have made a valuable contribution.

My last point will merely be to support the plea for pedestrian work. As may be known, I have occasionally done some speculative work. I recall giving a lecture to students on some particularly speculative matters, and they became most interested and fascinated. And so I closed with the advice “I am delighted if I have interested you in this, but do not do any work in such speculative fields until you have done some good pedestrian work so people know you are a real scientist and not just a crank.”

Naess: As Bondi indicated, sometimes philosophy of science is more of a burden than an asset for the creative scientist. I note not with reluctance but with delight that in science sometimes very unphilosophical minds do excellent things. In the case of physics, I venture to suggest that in certain years, from 1920 on, those who just said “Let us have more fun, doing some really good mathematical tricks,” could do it more easily because they did *not* have the worldview of Einstein. Even if they had a background of positivism and pragmatism, I would not be right in saying that they were mainly philosophically inspired, but “unphilosophicalness” may be of a philosophical kind, an *implicit* pragmatism, or practicalism.

Richard Popkin: I think the history of ideas thrives on the sort of pluralism Naess is advocating. If there hadn't been this sort of pluralism, things would be very dull because we would be just studying the same idea over and over again. Fortunately, there has been this pluralism, but I find in studying it there is always a tension between the sort of tolerant pluralism that Naess is advocating and the dogmatic pluralism that has gone on all the time. The contribution of the many views that have existed in the past seems to depend not on the fact that they tolerate each other but on the fact that they don't. But the dogmatism, the fact that people believe these things, really take them so seriously, claim they have the unique way to truth, has led them to produce the novel ideas that they have. If they were as tolerant as Naess would like them to be, I wonder whether they would really make this sort of contribution.

Pascal observed that Pyrrhonian scepticism is true as long as there are dogmatists, but as soon as there are no longer any dogmatists, this scepticism will become false.

Herman Tønnessen: Vigier remarks that the solutions of the most advanced problems are given by the scientists themselves, achieved in the laboratories, and he mentions one problem to which, he claims, the solution is now coming from laboratories, viz., the problem “What is life?”

First, I want to say that this model is not adequate. It gives the impression that one is either here or there, whereas the point is that in most cases we are focused somewhere in the middle, and that we shift, oscillating from one situation to another. The model overstates our definiteness of intention. This is misleading, as the whole thing is more like one enormous porridge of meanings and intentions.

Let’s take the problem of immortality, for example. If you say man is immortal, you can work out a formula. You can write “This is the maximum of tenability and this is the consolation value of your theory.” But in my opinion, it goes something like this. The more tenability, the less consolation value. But what do people do with “immortality”? One may, on the one hand, give it a definition that it is very likely to be *true*. Then, on the other hand, one could at the same time hold an idea of immortality that would be much different, but that has great *consolation value*. Thus, it becomes a porridge of intentions and meanings; and one oscillates imperceptibly between both extremes, which gives one the very comfortable feeling that both ideas are true: we are immortal, and we have the consolation. We are utilizing the vagueness and ambiguity of “immortality” to comfort ourselves.

Well, I would maintain that it is the same thing Vigier does. He is assuming unlimited definiteness of intention. Possibly his intention is, at one point, *A*, but he is tacitly assuming that it is at another point, say, *B*. Therefore, when he is talking about laboratory experiments as being relevant, they are only relevant to someone who has the level of intention *A*; but this is totally irrelevant for anyone who has the level or depth of intention *B*. And of course, somewhere between *A* and *B* there would be mixed feelings, and these are the mixed feelings I wanted to express.

Vigier: The question of life is a precise question that can be split into a series of problems and has indeed been put by biologists in quite a precise set of single problems.

Now we understand how the cell works, because we know that the

DNA is a code and the code gives instructions for all cellular chemical reactions. The living cell can be defined as a memory that reproduces itself.

This is the way in which a problem passes from the level of vague words into a precise formulation, and that is the way knowledge moves forward. Look at the way, for example, in which knowledge moved during the Renaissance, the vague way in which questions in astronomy and in physics were expressed before Galileo and other thinkers, and the precise way in which they left these problems.

Naess: If all fundamental views or theories about physical reality were to be considered in a critical atmosphere, it could only be done in an environment of tolerant pluralism. As regards the chances of professional maximal (or optimal) achievement in an atmosphere of tolerant pluralism, I share Popkin's pessimism. Dogmatism, narrow-mindedness, cocksureness, and fanaticism have sometimes been conducive to great achievements because they have made a researcher work out the consequences of a bright idea with greater energy. Intolerance does not protect just weaklings. Generosity and wide perspective is sometimes bad heuristic but always good cultural philosophy.

Is our great problem today lack of perfect achievements? Is it not rather the drying up of sources of a colorful multiplicity of views and attitudes owing to the worldwide integration of technical, "scientific" culture?

Vigier says that the problem of life is a series of precise problems. I would say, though, that there is no precise series. A hundred and fifty years ago, one of the central questions concerning life was whether organic matter could be explored and explained successfully by chemists and physicists. Tremendous scientific victories in organic chemistry, since Wöhler in 1829 succeeded in obtaining urea from ammonium cyanate, have decided that issue. It is not a living issue any more. There has been a shift of problems—many times.

Only specialists on Aristotle can make us aware of his frame of reference in *his* "physics." As long as we did not go deep enough, we interpreted it in terms of Galileo and the decadent "Aristotelian" physics of his time. Today—to our astonishment—we see a "physics" of Aristotle that is capable of a rejuvenescence, not as a physics in the contemporary sense, but as a view of physical reality and of the logic of "things." The discovery is analo-

PHILOSOPHY OF SCIENCE

gous to that of the independence of Stoic logic from the conceptual frame of—the same incredible genius—Aristotle. Both discoveries are feats of tolerance of diversity and careful inspection of fundamental assumptions, premises, and postulates.

Frederic Nef: I would only note that to distinguish is not necessarily to tear apart. To distinguish can be a means of bringing about agreement on a higher level and concerning matters that are more vital to man than those about which we disagree.

On the Structure and Function of Paradigms in Science

Classical History of Pure Science and Modern History of the Scientific Enterprise

In the 1930s the Marx-inspired scientist Boris Hessen with a keen interest in history scandalized worshipers of pure science in general and of Isaac Newton in particular by asking questions such as whether the need for a superior technology of navigation in imperialist England influenced the genesis of Newtonian mechanics. Worse still, scientists inspired by Freud asked whether the castration complex might influence logicians in their conception of negation. The usual straight stroke as a sign of negation is at the same time a symbol of a knife. In these cases, science is seen as something certain people do who are just like most other people, impelled by a mixture of personal motives or by impersonal structures such as systems of production. History of science until that time was largely seen simply as a quest for truth with its own logic, that of induction, deduction, verification, and falsification. Other factors were treated under the title of heuristics, the art of discovery. All very laudable and decent, and deserving the name of classical history of science.

The central function of natural science during World War II furnished what might be called “real,” highly professional historians with a strong motive to study the development of science with an intensity and a broadness of mind rarely, if ever, seen before. The historians inspired people with full competence in natural science to reshape its history. Instead of

This article was reprinted with the permission of Routledge, Taylor & Francis Group from *Theories of Carcinogenesis*, edited by Olav Hilmar Iversen (Washington, D.C.: Hemisphere Publishing Corporation, 1988), 1–9.

concentrating on internal, especially logical, aspects of science, the new study was, properly speaking, a study of the history of the scientific enterprise in its social setting, that is, the scientific community and the larger society.

The new look of science was known only to small professional groups until Thomas Kuhn published his *Structure of Scientific Revolutions* in 1962. With a brilliant, easily understandable terminology, he exposed certain aspects of the new trend in a way that inspired thousands of scientists in all major fields of study, including the social sciences and humanities.

In the years since the book's publication, his views have, of course, been subjected to criticism, and they have also been misrepresented and have invited extensions of which he did not approve. The work remains, however, a valuable source of inspiration, and his term *paradigm* irresistible.

Paradigms and Paradigm Shifts: Kuhn's Concept and That of Others

Kuhn's Concept

A "paradigm," as this term was introduced by Thomas Kuhn in 1962, is, roughly speaking, a way of "doing science." It is characterized by the acceptance or use of (1) a fairly definite set of explicit theories and hypotheses, (2) a much less definite set of fairly general assumptions, and (3) a practice of experimentation and research behavior.

An adequate description of a paradigm is not easily produced by scientists themselves practicing science firmly and confidently within the framework of their definite paradigm. Much is implicit and relates to unexpressed features of that practice. It is an essential job for a historian of science to propose adequate description of the characteristics of a Kuhnian paradigm.

The examples of paradigmatic changes in the Kuhnian sense are those produced by the great scientific revolutions: Copernicus in astronomy, Lavoisier in chemistry, Galileo and Newton in physics, and Einstein and quantum mechanics in physics and cosmology. It is perhaps typical that professional historians are not highly motivated to point out Kuhnian para-

digm shifts in history itself. If a historian of historical research makes a lot of fuss about a sudden major shift in how historical research is done, his or her colleagues will immediately concentrate on finding predecessors—and they mostly find what they intensely want to find or believe they find, as we all do. However, even historians agree broadly, I think, that after World War II there was a deep change in doing history of science. I call it a shift from doing history of pure science to that of doing history of the scientific enterprise—considered as a social activity on an increasingly gigantic scale.

There are some notable properties of a Kuhnian paradigm: A community of scientists rather than individuals may be said to work within the framework of a definite paradigm. The work normally results in the accumulation of suspiciously well organized knowledge. The careful elaboration and definiteness of the framework ensure easy comparability and interpersonal testability. The members of the community know what to do, how to judge what is good and what is bad work, what to accept, and what to reject as absurd, arbitrary, meaningless, unscientific, or unfruitful. This all sounds good, but there is something rotten not just in Denmark.

A detailed framework is indispensable, but it narrows down how to pose questions and it prevents attempts to create new frameworks. A growing crisis is necessary to motivate members to try something shockingly new, something that is not so much mistaken as absurd from the point of view of the Kuhnian paradigm. Growth of knowledge without crises is a bad sign.

Non-Kuhnian Paradigms

So much about the essentials of Kuhn's conception. What is relevant to the scientist's problems in cancer research is, I presume, scarcely paradigm shifts on the grand scale of the Copernican revolution or even the transition from phlogiston chemistry to that of Lavoisier. Olav H. Iversen and E. G. Astrup claim that they are "fully aware of some of" their own "paradigms, prejudices, and shortcomings" (Iversen and Astrup 1984: 51). The main use of the term *paradigm* in Kuhn's text is such that we work within one paradigm at a time and are *not* fully aware of it. I think it is fruitful to

use the term in a fairly wide sense, if not quite as wide as Iversen and As-trup in the above quotation. I shall concentrate on problems concerning dominance and shift of dominance of a theory with its particular concep-tualization, and the concomitant practice of research, including experi-mental designs.

First let us ask, How is strong dominance possible in a community of presumably independent, open-minded researchers? Is it because a theory has been verified? The answer of today's philosophy of science—or meta-theory of science—is, Not at all!

The negative answer is most easily understandable when we concen-trate on the relation between theory and observation. The total evidence for and against a theory is, of course, not only of an observational character, but I here deliberately limit myself to observation.

If by "theory" we mean a set of fairly general, abstract statements, there is no finite number of observations that can verify it. A theory about the function of insulin in human bodies is not limited to human beings presently living or to definite samples of insulin. Therefore, even billions of tests cannot verify the theory in a logical sense of proving its truth. The ra-tio of tested cases to possible cases remains the ratio of the finite to the infi-nite. Strictly speaking, a theory is not even made more probable by adding positive observations.

There is today a new factor. The ways of observation mostly include the use of immensely complicated instruments and machinery. A sentence written in an observational journal, a plus or minus or other short symbol, is only relevant to the test of the theory if the working of the instruments has been flawless at the moment of the observation. In short, there is no end to the premises assumed to be true or tenable if we say that we have verified a theory.

The distinguished philosopher of science Sir Karl Popper is reputed to have rejected the practicality of verification but retained falsification. If we look at a hypothesis such as "All ravens are black," a simple observation of color plus the help of a taxonomist may falsify the statement. Here is a raven, we say, and evidently it is green. However, the hypothesis "All ravens are black" is a simple generalization of something rather directly ob-servable, and not what we call a scientific theory.

Suppose we make an observation that contradicts what we wish the

experimental setup to find. Is genuine natural-science theory then falsified? It is rather pretentious to say that. There may be a lot of weaknesses in our experimental setup, and perhaps the phenomena observed belong to the fringe of the intended field of validity of the theory. Suppose, however, that there is in the relevant community of scientists no doubt that it *is* a genuine disconfirming instance. From the point of view of logic, the theory is then falsified only if we suppose the community is right in its conviction. The curious conclusion is then that practically all established theories of high reputation are falsified, because there is at least one instance of disconfirmation, often unpublished, that we simply cannot rule out as spurious or misleading. I do not think we should say that all well-established theories are falsified, but instead say that there are some disconfirming instances that we cannot account for among a wealth of confirming ones.

In the above argumentation I use the term *established theory*, and now we perhaps reach the heart of the matter: the logic of scientific research is important, but the life of science, the activity within today's scientific enterprise, is not logical in any sense! What currently are the most successful theories are not the theories that are verified or shown to be probable, and the competing theories are not falsified or shown to be less probable.

When we try to understand the reasons for the life, death, or dominance of theories in natural science, what we may call the Mach-Duhem-Poincaré theorem is central. A somewhat long but precise formulation of the theorem is:

Given a theory T and a set of confirming observations O , whatever the number and kinds of observations, there are potentially an indefinite number of theories incompatible with T that also are confirmed by the observations O .

By two theories T_1 and T_2 being incompatible is here meant that the joint assertions of both of them yields a logical inconsistency.

The extremely simple general reason for the validity of the Mach-Duhem-Poincaré theorem is the availability of incompatible premises yielding the same conclusion.

By a theory T , I shall in what follows, as in the preceding, denote a

causal or statistical, general, abstract statement without temporal limitations, for example the limitation to saying what *has been* the case rather than what *is* the case. The succession of simple events such as light signals can be directly observed, but causes cannot.

Let me illustrate what cannot be repeated too often and that explains a lot about the anatomy and physiology of paradigms.

The considerable distance between theory and relevant observations can be illustrated by placing *T*, for theory, at the top of a treelike figure and *O*, for observation, at the bottom. The premises of the basic logical relation of derivation proceed down from top and branches. The highest branches contain abstract theories of logic, mathematics, physics, chemistry, and other abstract aspects of science that are presumed to be valid when testing *T*.

Farther down, the branches contain hypotheses from particular fields in the neighborhood of the theory *T* that also are presumed valid. The lowest, most numerous pairs of branches contain detailed descriptions of the particular situation, for example the experimental design and setup, the operations carried through by presumably competent people, and all other more or less directly observable conditions of each particular, singular observation. Most of the items presume the validity of abstract theories, the apparatus to measure time, the microscope, and so on.

A definite well-arranged test by observation is one that either provides an instance of confirmation or an instance of disconfirmation of the theory. Adding instances of confirmation does not yield verification, nor does adding instances of disconfirmation yield falsification. Seen from a logical viewpoint, why is this?

Compactly reformulated, it owes to the circumstance that the statement *T* is only one of innumerable premises that together furnish the derivation of *O*, that is, predict *O*. If we do not get the observations we should have, if the theory is correct, why is it then not falsified? Simply because of one or more of the innumerable other premises that *T* may be wrong. The experimental setup may contain a flaw, that is, one of the statements on the lowest branches may be false, just to mention one kind of possible weakness.

If we get what we predict, it does not directly concern the validity of *T*

because innumerable other theories inconsistent with T are also, according to the Mach-Duhem-Poincaré theorem, compatible with the particular observation O .

Let us consider an analogy:

From	All fishes are warm-blooded
and	All whales are fishes
we derive logically	All whales are warm-blooded

Here two wrong premises furnish a valid construction.

Every confirmatory instance of T may in principle be attributable to untested faulty assumptions; the same may hold of every disconfirmatory instance. In short, whether we observe the predicted O or something entirely unpredicted has only a very distant relation to the validity of T .

The two-stage theory of carcinogenesis formulated in a concentrated fashion by Boutwell, Urbach, and Carpenter (Iversen and Astrup 1984: 53) contains twenty-seven short sentences of more or less abstract character. Few theories, carefully formulated, can be made any shorter. The introduction of a measure of probability—for example, an assertion that the probability of the theory is .21—can scarcely be of any use, if practicable at all. Tests are scarcely able to confirm or disconfirm even a small number of assertions of the theory. More serious is the tendency of untested research practice (experimental design, technology) to be stereotyped in such a way that theory hardly can be disconfirmed. “Probability” measured by confirmatory instances approximates 1 but is totally misleading. Talk about the probability of a theory being true may be acceptable at a superficial level, but talk about the probability of a paradigm is not acceptable, even on that level. The whole tree of assumptions is relevant. A probability of the sentences of theory T cannot be singled out and isolated from the sentences expressing the complete mass of assumptions. Theories and paradigms have complex properties that motivate their acceptance or rejection. Probability in any precise sense does not belong.

We are *in practice* justified in saying sometimes that a theory is heavily disconfirmed or highly confirmed. Practical research has, and must have, considerable distance from logic. This is not generally admitted, however, so we see researchers treat theories as if simply verified or falsified, that is,

simply *shown* to be true or *shown* to be false. To a degree, this talk is good for the moderate stability of the scientific enterprise, and it is also a source of happiness for scientists. It is satisfying to verify a theory and contemplate how wrong the opponents are.

I shall end this deliberately repetitious treatment of the relation of theory to observation by mentioning a humorous example. The very learned non-astronomer Velikovsky derived from premises utterly false or improbable, according to the astronomical establishment, the conclusion that the surface temperature of Venus is several hundred degrees hot. At the time there was a lot of laughter among astronomers, but then actual observations were made, and Velikovsky's conclusion verified in the opinion of astronomers. It was slightly annoying to some of them, but mainly because of the illusion that when a logically valid inference is made from a set of premises, and the conclusion is accepted as true, one should, according to scientific methodology, take the premises rather seriously. According to the Mach-Duhem-Poincaré theorem, however, we need *not* take the particular set of premises seriously.

The above logical excursion is astonishingly well adapted to explaining the frequent dysfunction of paradigms. Successes of a theory in explaining and predicting strengthen the opinion that the long series of confirmatory instances reveal the truth or probability of the premises, and among them the theory formulation itself. This creates an untenable prejudice in favor of the theory and favors its domination.

Furthermore, the successes strengthen the tendency to define the terms used in the theory in terms of the particular processes of testing and confirming it. This decreases the likelihood of disconfirmations, not because of the large area of validity of the theory, but because the so-called operational definitions have narrowed down the potential area of disconfirmation. The resulting head-shrinking of the supporters of the theory goes unnoticed because conceptual analysis is not a main concern of the practical researcher.

Fruitful concepts are mostly vague until made more precise by attachment to processes of testing and observation. Such attachment is utterly important for science. It is useful to recall perhaps the most epoch-making operational definition of the century, that of simultaneity advocated by Einstein.

We all have an intuitive notion of what it means to assert that two events *A* and *B* occur simultaneously. The relative velocity of movement of the bodies upon which the events happen is clearly irrelevant. Physics, however, requires a testability of the assertion and this implies the use of light. The universally accepted definition of simultaneity is now in terms of the remarkable properties of light. Completely counterintuitive but “operationally” satisfactory!

This example has been mentioned for only one reason: to illustrate the compelling force of attaching concepts of a theory in natural science to processes of testing that theory. (The example is not so good in illustrating a second important point: when the theory is attached to established procedures, alternative procedures are ruled out by definition. In cancer research this may be of practical importance, but in theory of relativity there do not seem to be possibilities other than attaching concepts of time to that of light. Very wonderful and strange, but so it seems to be.)

In general, the successes have the effect on most researchers of stabilizing the gigantic set of, in part, rather arbitrary assumptions that they have made. In other, simpler words, the successes stiffen what one simply takes for granted. This stability is one of the main reasons for talking about a tradition of research or, today, talking about a paradigm. It belongs to the anatomy rather than the physiology of the paradigm. To the physiology belongs the function of auxiliary hypotheses. When a theory does not quite live up to its good reputation, assumptions are added that quite consciously are made to help the theory get confirmed in new areas or in recalcitrant subareas. If the auxiliary hypotheses help, their ad hoc character is easily forgotten, and by a sort of strange feedback, the success adds to their reputation. They are now believed to be valid on their own. They furnish another protective wall against the onslaught of serious questioning of the whole Christmas tree of assumptions.

In all I have said I have used a logical model, the Christmas tree of derivation (or inference) from assumptions. Kuhn and his followers have gone into psychology, social psychology, and in general, the genesis of paradigms of the grand type. I should perhaps add that such analysis is as pertinent as the logical, but talking to researchers in the present and not about the past, the logical and conceptual analysis must be the point of departure. It takes the actual views of the researchers seriously and just points

PHILOSOPHY OF SCIENCE

out the large freedom of choice owing to absence of strict verification and falsification of theories. All is hanging in the air, more or less. One never need feel closed in because so much is peacefully taken for granted by most of one's excellent colleagues. The status of established so-called facts is not logical and conceptual; it is more like the establishment of habits and customs. With today's intricate processes of observation, the purity of data is less obvious than ever. Scientists are entitled to go to bed wondering, and to enjoy wondering. They may indulge in an open-mindedness toward alternatives that sees few limits.

Science as Behavior: Prospects and Limitations of a Behavioral Metascience

Metascience from the Far Outside and from the Near Outside

The various sciences of religious prayer do not presuppose the existence of any gods. If a religion with a *G* is studied, the researcher does not have to be a believer in *G*. The sentences he writes have meanings, truth-values, and designated objects that are independent of the question of whether *G* exists. The phenomenologist of religion does not study the believer's relation to his god, but the believed relation. If the believer reports that lately his prayers have been heard and rain fell on his lands, this is used as material, as object, for analyses of various kinds. As to the validity or truth of the believer's assertions (insofar as they are assertions), the phenomenologist of religion retains his *epoché*. The same holds for the existence of any objects of religious worship.

How far is it possible to maintain such a detachment and still understand what is supposed to be studied, namely, religion?

The programs for a science of science that are the primary concern of this paper are characterized by looking at a scientific enterprise (or a part of it) as an object to be studied "from the outside," not as an undertaking to engage in and improve upon. They are phenomenological insofar as they maintain, more or less, an *epoché* in the sense just described.

The qualification "more or less" is essential because there are theoretical as well as practical limits to the degree and extent of attainable alienation from the claims of scientists. Beyond certain limits, it becomes more

This article was reprinted with permission from *Scientific Psychology: Principles and Approaches*, edited by B. Wolman and E. Nagel (New York: Basic Books, 1965), 50–67.

and more doubtful whether what is studied is still science. After all, the practicing scientist explains what he is doing in sentences presupposing the existence of a vast number of objects—elementary particles, matter waves, stimuli, drives—and what he refers to as the scientific enterprise is defined in terms of intentions and aspirations.

On the other hand, the basic aim of metascience as discussed in this article is to study a scientific enterprise without engaging in it. The scientist himself not only uses but also mentions sentences in his own discipline. His work consists partly in comparing contemporary theories, which implies neutrality within certain narrow limits. When these limits are widened, the conception of metascience envisaged in this article emerges. An answer to “What is cosmology?”—as a piece of metascience from the near outside—would describe the contemporary cosmological undertaking but would take part in assessing neither the truth-value nor the “fruitfulness” of the various theories, nor of the specific presuppositions of that discipline. This requirement, if stated clearly, implies that the metascience cannot even presume that there is a cosmos such as is described by the cosmology under study.

Falsification and rejection of a particular theory should not occasion retraction of anything said in the genuinely metatheoretic description of the theory and of its prior acceptance. However, because the falsification of a theory sometimes also undermines the reasons for accepting the existence of certain objects or entities in terms of which the theory is described, the program of the scientist of science must be to eliminate sentences that presuppose their existence. It will, however, retain names naming the expressions used in the theories studied. “Cosmology,” for example, may be used in the metavocabulary as a name of the expression “cosmology” in a cosmological textbook.

To avoid the very special problems confronting a sociology of sociology, a theory of learning of theory of learning, or a logic of logic, I shall limit the expressions “a science of a science” or “*x*-ology of *y*-ology” to cases in which *x* and *y* are different. That there are special problems connected with “*x*-ology of *x*-ology” does not impress scientists so much as philosophers. Thus, E. C. Tolman (1932: 430), the purposive behaviorist, says that he himself asserts “that all human knowledge, including physics and purposive behaviorism and our own present remarks, are but resultant of, and limited by, human behavioral needs and behavioral capacities.”

I shall discuss the attempts that have been made to supply the conceptual tools for a certain kind of factual science of science, the behavioral. The discussion will, I think, bring to light considerable theoretical difficulties inherent in the programs of such a science of science. Whatever the ultimate limitations of a molar behavioral view and way of attack, however, I believe that this approach will continue to be a potent agent in the carving out of new fragments, disciplines, or departments of science.

We are in a position to describe a psychological system as an object only when we place ourselves within a frame of reference that is different from the ultimate, specific premises and rules of that particular system. This does not necessarily force us out of any psychological frame of reference whatsoever (see S. Koch's *Psychology: A Study of a Science*, and similar undertakings). The studies from the near outside are not independent as to general presuppositions of the science. The objects of the science are presumed to exist. A revolutionary change in beliefs concerning these objects might therefore affect the acceptance of the metascientific theories from the near outside.

Research Behavior Units: A List of Scientific Doings

Behavior conceptions are generally pragmatic and functional. They try to focus on the deeds of the researcher and describe his theoretical results in terms of achievements and adjustments, such as bringing order into something.

In one sense, the scientific enterprise is described by its practitioners themselves in terms of acts or deeds. These descriptions may be improved upon by researchers looking at other researchers from the outside, but still participating in general. This aspect is what Albert Einstein (1934: 30) had in mind in his maxim, "If you want to find out anything from the theoretical physicists about the methods they use, stick close to one principle: don't listen to their words, fix your attention on their deeds."

The behavioral metascientist will find that the scientists themselves have, in part, a vocabulary that seemingly describes a behavioral aspect of the general scientific enterprise. Let us suppose he takes over the terms in this vocabulary.

The initial behavioral metascientific vocabulary will accordingly con-

tain terms in general use among practicing scientists: observing, experimenting, measuring, classifying, describing (in gestures, writing, or speech), explaining, predicting, discovering, inferring, guessing, interpreting (symbols, processes), providing, deducing, calculating, justifying, presupposing, defining, discussing, refuting, accepting as working hypotheses, posing a problem, proposing conventions, accepting conventions. In what follows I refer to this (fragmentary) list as the list of “kinds of doings.”

The terms themselves permit interpretations in different directions, some of which lead outside the behavioral aspect of science. The location of the boundary depends on the interpretation of the key terms *behavior* and *science*. “Located outside” is a strictly logical, or formal-logical direction. For example, logicians of science such as Karl Popper stress the view that they are concerned with relations between statements of science, such as implication, and that terms like *observe* and *falsify*, as used in the logic of science, have nothing to do with processes in time, as do psychological events. In studies that are not logical in a strict sense, but often so called, the terms of the list of doings are likewise taken in nonbehavioral senses. Rather, one is supposed to study the *logic* of the use of “observe” and “falsify.” What the scientist actually does need not be described in the terms of his factual science.

Even when (as throughout this paper) “behavior” refers to the behavior of *living* beings, there is an institutional, more or less purely sociological sense of each of the words listed that falls outside the behavioral aspect of science. Thus, if one were to contribute to the institutional sociology of science, the accepting or rejecting of conventions would certainly be central themes, but the subject of inquiry would ultimately be defined, not in terms of behavior, but in terms of institutions. Furthermore, there may be a phenomenological interpretation, essentially bound up with the philosophy of Edmund Husserl or with related philosophies.

All the terms of the list, however, at least in one plausible interpretation, do refer to doings of human beings as individuals or groups. The characterization of observing, experimenting, and the others as “doings” is appropriate and significant in various degrees. Concerning explaining as a kind of doing one may, for example, ask, Who was it that explained this phenomenon? Did he explain it completely? When did he start? Has he yet finished? Have others explained the same? How did he explain it? Did he

do it well? Did he do any deducing in explaining? Why did he do it as he did? Could it be explained better otherwise?

Approaching his subject, the metascientist announces his intention to study some area or aspect of the scientific enterprise. The words he uses when he does this are not yet those of a metalevel; we may conveniently conceive of him as a scientist announcing his intention to other scientists in their common jargon. He may, for example, say that he intends to “study our explanations as explanations.” In spite of initially *using* the term *explaining*, the behavioral metascientist is committed in principle, when carrying out his intention, to taking the occurrences of that term in speech and writing *as objects*.

What this implies is conceived differently by metascientists of different philosophical inclinations. To some it implies abstraction from intended meanings and a focus on the extensional aspects—for example, on the string of letters e-x-p-l-a-i-n-i-n-g, or on a certain phonetic unity. By others, among them some phenomenologists of Husserlian inclinations, the object “explaining” is taken as an intended meaning.

If it seems convenient to the metascientist, he will continue to use the term *explaining*, but as a common name for occurrences of the term *explaining* in certain scientific contexts, or as a unit of intended meaning. To obtain fluency of use on a new level, he must undergo a process of unlearning or “extinction,” which poses practical difficulties that I shall not discuss. Analogous difficulties have been discussed elsewhere, for example, in literature dealing with the unlearning of natural or physical geometry when starting on pure or abstract or axiomatic geometry. I shall here assume that the extinction problems of a metascientist can be solved and that his objects can be named and identified by using the ordinary terms of the practicing scientist with new metalevel meanings.

One of the best surveys of pertinent behavioral literature is to be found in Campbell (1959). It refers to works by D. Bakan, G. Bergmann, L. Bertalanffy, E. Brunswik, D. T. Campbell, H. Feigl, W. Köhler, K. Lorenz, R. K. Merton, J. Piaget, G. Polya, E. C. Tolman, B. Whorf, and others. Most of these contributions have been made under the spell of a particular ideal, that of nomothetic science. There is a premium on general behavioral *laws*, as these quotations attest: “Categorizing is the means by which the objects of the world about us are identified.” “[B]y categorizing as equivalent dis-

criminally different events, the organism reduces the complexity of its environment." As formal scientists studying the research behavior of a scientist, we should investigate inventions in the light of his discriminatory behavior and capacities in general, his perceptions ("what he sees"), and his discriminations of degrees of convenience: "We invent logical systems such as logic and mathematics whose forms are used to denote discriminable aspects of nature and with these systems we formulate descriptions of the world as we see it and according to our convenience" (see Bruner 1956: 7–21). "Attainment of concepts" is defined as "the behavior involved in using the discriminable attributes of objects and events as a basis of anticipating their significant identity."

It seems more hopeful to look for structural and phenomenological accounts, taking behavioral science of science as primarily an idiographic discipline.¹

Value of a Total Behavioral View

By a total view of science, I mean a perspective or vision that, at least implicitly, embraces any part whatsoever of science as well as science as a whole.²

The implications of a total view, for example of a logical or sociological character, may in principle be carried through consistently in the form of an elaborate construct, or emerge without being noticed by those who share the view. Thus, a psychologist immersed in research on general features of learning processes, using rats in a more or less natural environment (not inside elaborate machinery as has been done recently), will in the long run, or remarkably soon if intensively engaged, acquire a very special way of looking at living beings as systems of behavior. For the psychologist or philosopher who is interested in basic ways of looking at and conceiving the world, any special views generalized or inflated into total ones are of great interest. A behavioral total view has an intrinsic philosophical interest.

The professional behavioral point of view, like many other professional views, has a strong intuitive component. In some researchers (Brunswik, Naess, Tolman), it has had the character of a vision. To those who do not share the intuition, more or less general statements about science as behavior that are obvious to the behavioral scientist sound far-fetched and un-

sound. For example, to look at *proving* as a piece of behavior or doing is rather rare and, to most, rather unnatural. When it is looked at freshly and consistently in this way, however, certain relations are immediately evident that are sometimes judged to be nonexistent by the philosopher or the mathematician, who habitually takes a logical point of view in science of science.

The selection of the terms of rule formulation is made on the basis of existing rules and habit formations among the prospective users of the rules by the rule senders. If any major variation in habits occurs, the rules will mislead or, rather, result in indefiniteness. This will be discovered, for example, by a contradiction or a non sequitur within the formal system. "A calculus is never completely regulated [*geregelt*] in the sense that the rules for manipulating the sign complexes prescribe perfectly unambiguously the way of manipulating" (Naess 1936a: 152). Kaila (1941) argued that this view does not make sense, since we have proofs of the completeness of the calculi or propositions and of the predicates. When the rule giver and the rule follower are seen behaviorally "from the outside," however, the incompleteness is intuitively clear. It is also clear that "behavioral incompleteness" is different from incompleteness as conceived by a participant in logical or mathematical research. Kaila's argument is conclusive only if the metalevel intended in a consistent behavioral account of rules is utopian or impossible in principle. If the latter is the case, the behavioral "vision" is self-deceptive, and Kaila's view is correct.

Historically, the behavioral point of view gained its strength from a dominant trend in psychological methodology stressing the importance of defining the objects investigated in terms of observables. "Behavior" came into favor in part because of a kind of maxim that a person's behavior is completely and conspicuously observable. Because of its genesis, the behavioral point of view might be considered to be infected with a latent "observationism." There is, however, no necessary connection between taking a behavioral point of view and "observationism" as defined by Peters (1951), for example. The behavioral point of view is independent of operationism and logical behaviorism; it does not imply that research activity must start (in time) with observation rather than with formulating a problem, with getting an idea or hunch, or with a need to test an idea already there. What is implied in the idea of behavioral science of science seems rather to be a

view of the researcher from the outside rather than as a colleague. The expression “from the outside” is to be taken in the metaphorical sense of “as a nonparticipant in the researcher’s special doings” rather than in the sense of concentrating on his gross overt movements.

In practice, for a nonparticipant the possibility of saying anything of interest about the researcher seems to depend on being or at least having been a colleague. The behavioral “vision” therefore depends on a process of extinction (in the terminology of learning theory); and because of the large scope of this extinction, it is tempting to say that it depends on a process of alienation (*Entfremdung*).

The value, then, of a behavioral view as a total view has several components: (1) as a philosophical system or subsystem of the “alienation” class, (2) as a means of keeping apart and working out in isolation the logical, factual, and other aspects of a vague or general question, and (3) heuristically, in suggesting concrete behavioral research projects.

The Behavioral Approach and Behaviorism

The behavioral accounts of science are highly sensitive to the use of the term *behavior* in the conceptual structures of *psychology*. We must tackle the problem of what behaviorists mean by behavior.

To eliminate certain confusions, it should be borne in mind that behavioral scientists have not intended to follow the “ordinary usage” of *behavior*. In the vernacular, “to behave” is usually qualified without reference to definite forms of behavior. The answer to “How does he behave?” is not “He is running” or “He is testing his hypotheses,” but the provision of adverbial qualifications like “admirably” or “badly.” To report on behavior and separate it from any evaluation is itself to behave rather strangely.

Let us inspect an astute behaviorist’s comments on an example of behavior.

According to B. F. Skinner (1953: 15), “Narrative reporting of the behavior of people” is “part of the sciences of archaeology, ethnology, sociology, and anthropology,” but “only the beginnings of a science.” As an example of narrative reporting about behavior, Skinner uses the highly instructive sentence, “She slammed the door and walked off without a word.” Such a remark, however, is typical of a participant in social events,

not of a scientific observer. Another witness might have reported the “same” event as “She ignored his question, moved slowly toward the door without looking at anybody, and disappeared.” Still another might have reported that “After this, she did not do anything—she just left.”

If every truthful, conscientious participant’s account is taken as an observational basis, behaviors will be strange, multidimensional events indeed. On the other hand, if a certain selection is made—for example, if “She shut the door” is preferred to “She slammed the door”—a process of behavioristic purification is started that seems to lead to absurdities. What would be the correct, nonparticipatory description in which only the public, molar behavior itself is reported?

Let us imagine that an ordinary behavioral description is made more and more detailed and complete. Will it ever include a kinematic description in terms of smaller and smaller segments of behavior? That is, *prima facie*, very unlikely. Let us try to formulate a complete behavioral description of an event, starting with an everyday description—let us take “She slammed the door.” Is it true, as Skinner argues, that behavior is a difficult subject matter for science “because it is extremely complex”? It would seem that if the event, which took place within the interval of one-third of a second, were described kinematically in a ten-page report as a *complex movement*, the report, for all its length, becomes no more accurate as a description of her slamming the door. The real complexity is related to the “social structure” that may or may not make an event a case of slamming.

Edwin R. Guthrie (1935: 29 ff.) uses terms such as “the continuing flow of behavior” and “total behavior” and suggests that science cannot cope with it in its entirety. This suggests that Guthrie wishes to define behavior in terms of movements.

What is indeed difficult is to make a *report* of the event “itself” that can be used as a *common basis* for various interpretations, some in terms of slamming, others in terms of mere shutting. I suggest that an “objective” report by a specialist in acoustics and a specialist in limb movements, “on the movements and the resulting noise,” would scarcely constitute a report that could be used as such a common basis. On the other hand, if the participants’ reports are taken as ultimates, one may no longer speak of different accounts or interpretations or meanings of *the same* event or behavior.

Guthrie (1959: 165) has stressed that “the hope that response could be

treated just as movements in space" failed to carry us very far toward the understanding of behavior. "Patterns of stimuli and patterns of response have their psychological significance and usefulness tied to their patterning—pattern as pattern must be recognized and dealt with." *Can pattern as pattern be recognized?* It seems that a pattern must be a pattern *of something* within or on something. Guthrie's critique of "an entire generation" (Koch) of stimulus-response theorists leaves us in doubt as to what will be the subject matter of the next.

There is, of course, no reason a priori why "behavior" and forms of "behaviors" cannot, in spite of unorthodox semantics, be useful key terms within (so-called) behavioral science, that is, as terms suggesting a witness's view from the "near outside." However, behavior must then be dissociated from reports about "movements" and associated intimately with terms such as *doing*. "What is he doing now?" rather than "What is his behavior now?" is what is answered by accounts of the kinds that molar behavioral scientists class as observational. The usual answers about what somebody is doing are quite straightforward, in terms of the participator, at the witness level, not at the level of a complete stranger. Projection tests show that different people will answer the question "What is he doing?" very differently, "seeing" different doings. The resulting accounts are understandable and of interest to the acting person as true or false accounts of what he really is doing. If a report on mere movements is offered, he may legitimately protest, for the result is to substitute movements for doings. The same kind of protest is justified if the doings are in terms of other "far-fetched" frames.

Even in the cruder forms of behaviorism, "learning," "searching," "finding," and "making hypotheses" were not defined or conceived as classes of movements. In the field of rat learning, it was early stressed that the learning of a maze is not the establishment of any kind of definite sequence of movements or overt behavior fragments. In certain experiments mazes were flooded, yet rats easily found their food by swimming in spite of having learned them by running. Similarly, a description of research in terms of behavior must not be expected to consist of descriptions of concrete pieces of behavior (behavioral "episodes") corresponding to sentences of the kind "N. N. now falsifies the hypothesis *H*" and other sentences referring to the doings of scientists.

There is some truth in Ryle's contention that there has been a kind of "official" program in psychology to investigate states of consciousness as such, but since the famous article by William James (1904), "Does 'consciousness' exist?" the mind-stuff theory has not had much influence in psychological research. The notion that immediate experience can be investigated as mind-stuff and separated from the "material" world was not taken seriously, and molar behaviorists rejected the dichotomy between "sense data" and "physical reals."

So much in defense of the behaviorist's general view. As regards the *results*, the view suggested by R. Peters (1951), that these psychologists were rather sterile, can scarcely be taken seriously in light of the history of psychology since World War II (see Steward 1954).³

My main contention in this section is that certain psychologists who called themselves behaviorists worked within a conceptual framework that proved adequate in dealing with large areas of problems and that directly furnishes a workable research program for a factual science of science. It will not, however, automatically be a science of science at a genuine metalevel, studying the scientific enterprise as an object, but rather studying additions to science at the object level. A program of step-by-step elimination of participatory assumptions is called for, starting from "nearest outside."

A scientific enterprise is seen from the near outside within a contemporary framework more or less congenial with the enterprise studied. This implies that there is, strictly speaking, no "actual scientific practice" or "methods such as are actually used" to be investigated behaviorally from the far outside. There are only practices as seen by participants in research, more or less colored by definite traditions and schools, and by prevailing terminological and conceptual idiosyncrasies and ideological convictions. The slogan "Do not listen to what the scientist says, but study what he does" is misleading. One must listen and take part.

Later I shall turn to certain grave difficulties confronting those who try seriously to implement a program of a science of science that consistently occupies a genuine metalevel. One of these difficulties can be clearly stated with reference to the notion of "operation," a central notion in behavioral descriptions of the scientific enterprise.

The Behavioral Approach and Operationism

According to operationism as defined by P. W. Bridgman, a concept is identical with a set of operations, and if a term is used for several operations, it expresses several operations.

An operational account of a scientific term or assertion is also a behavioral account, provided that an operation is a kind of behavior. Operations are performances; they are carried out correctly or incorrectly and with greater or lesser skill. To make operations a subclass of behaviors, we must presumably interpret this term in the direction of "doings."

Both the theory of relativity and quantum physics have contributed to a strengthening of behavioral tendencies in describing science. Physicists have explicitly distinguished between the intuitive pseudomeaning of a term, based on appeals to the imagination, and physical meaning in terms of certain doings such as measurement, which not only in theory, but also in practice, may be carried out. In the case of quantum mechanics, invocation to manipulate certain equations according to a set of rules has often replaced appeals to the imagination. The retreat from *Anschaulichkeit* has been a retreat from "connotative imagery" in the sense of the behaviorists.

If it were required of all physical theory that all terms be expressive of *physical* operations, modern physics would not fulfill the requirement: some terms are mathematical. Operationists characterize mathematical concepts as sign manipulations. If a physical theory need be testable only as a whole, its terms then need not all be expressive of physical operations. The mathematical manipulations, especially in the form of derivation operations, can be shown to furnish contact between the physical concepts of the theory and the operations of testing, such as measurements. As I understand it, a necessary condition for tenable operationist accounts of modern physics is that testability be required of a physical theory (in the form of a hypothetico-deductive system) only as a whole, not separately of every proposition contained in it. If this weaker requirement is made, the operationist can meet the argument of Einstein (1949: 679) against operationism. He complains that operationists overlook the point that a theory, in order to be physical, needs to imply only *some* "empirically testable assertions in general."

The operationist account of physics is clearly different from a logic of physics in that the operations are conceived as observable activities. One is

to *look at* the physicist and see how the different kinds of measurements are carried out. The operations are not conceived as rules governing observable activities. If the ultimate characterizations of an operation were to include a reference to a rule, this would spoil the postulate of observability. Rules are not observable activities.

Study of the operationist influence shows very clearly the danger of practicing scientists' taking metascientific theories seriously as guides for their own activity. Thus, the operationist influence in psychology has in part resulted in severe inhibitions of imagination in the researchers. In "heuristics" any kind of introspection, myth formation, or cognitive imagery may be of help to the theorist. Even in taking up the question of testability, there is room for much of this as long as the Einsteinian requirement, broadly approving as empirically testable any theory that connects at least at one point with nonverbal operations, is satisfied.

Strangely enough, it is among scientists of behavior that the idea of Bridgman's operationism as a kind of generalization from observation of scientists gained most enthusiastic support. Thus, S. S. Stevens (1953: 160), in a paper avidly read by psychologists, wrote that Bridgman in an "empirical spirit observes the behavior of his colleagues and finds that what is considered an *explanation* 'consists in reducing a situation to elements with which we are so familiar that we accept them as a matter of course, so that our curiosity rests.'"

With this faith in a nonpsychologist's capacity of observation as a basis, it may be understood that Stevens felt he was "witnessing the birth of a new discipline: the Science of Science . . . science-makers . . . asking themselves how they make science and turning on that problem the powerful empirical weapon of science itself" (ibid., p. 159).

The foregoing metascientific account of explanation implies not only that curiosity in scientists can be identified as a general attitude, but that a behavioral study can reveal the difference between "curiosity whether *p* or not-*p*" and "curiosity whether *q* or not-*q*," where *p* and *q* are sentences in physics. Further, it implies a criterion-measure of "familiarity" and of "reduction of situation." All these concepts would then have to be either defined in terms of scientists' doings or connected into a unified theory from which some empirically testable propositions might be derived (using Einstein's minimum requirement).

It is not here suggested that the idea of an empirical behavioral meta-scientific discipline of explanation is completely utopian, but that its implementation presupposes questions of observation and testing that must be faced squarely before anything is accepted in the form of general results. Even if, through observation of behavior connected with research occurrences of a term *T*, we are led—and exclusively led—to observation of operations, tremendous difficulties confront the behavioral observer in deciding what constitute the specific characteristics of a definite kind, *B*, of behavior unit or doing. The question “Exactly what is he now doing?” is of a difficult type, normally capable of adequate answer only from extensive knowledge of the situation, which again implies knowledge of many happenings before “now.” Operationists presume that they have the capacity of giving adequate (definite) answers, because they presume the existence of an inventory of definite, identifiable operations, each having some unique characteristics: “We must demand that the act of observation equivalent to any concept be a unique set, for otherwise there are possibilities of ambiguity in practical applications which we cannot admit” (Bridgman 1948: 6).

As an example, let us take an answer to “What, exactly, is he *now* doing?” formulated as “He measures the simultaneity or lack of simultaneity of two events far from a stationary clock” (see Einstein 1923: 38). Exactly which traits or fragments of an actual sequence of behavior within a specified region of time and space are relevant and which irrelevant? Observing a scientist at work, ten bystanders who are not instructed about what the scientist is doing, or that he is a scientist, may each note down a hundred observations, each from his own perspective or interest, and none referring to any traits mentioned in the ordinary, conventional description of measurements of time. The definition of the behavior *B* (or, more precisely, of the kind of behavior) will be able to include reference to only a small number of traits. A *principle of elimination of irrelevant traits* is needed, and such a principle cannot be found by an observer who has no education in physics. Bridgman (1949) indirectly testifies to the difficulty of operational analysis when he credits Einstein with seeing the importance of certain details in measuring that “no one had had the imagination to formulate” or “to see that they might be significant.” Normally, students gradually learn to know which traits of behavior fragments are significant, that is, which traits are considered significant among contemporary experimental physi-

cists. The learning, however, does not include learning to give a verbal report stating explicitly which traits are significant. The behavioral metascientist could not get his data regarding the physicist's doings or behavioral units directly from the physicist by asking him, even if, as a metascientist, he were able to do so without giving up his metalevel.

The audible word-event "rascal" varies acoustically in an extremely complicated way. No researcher has been able to characterize acoustically the limits of satisfactory pronunciation of that term; the relevant acoustical studies are guided by phonetic knowledge. Similarly, exploration of forms of research behavior must proceed from an intuitive understanding as a "colleague" of the researcher studied. The absurdity, or at least extreme difficulty, of exploring in the other way (starting from more or less narrow behavioral observations and trying to arrive at the description of research units such as "testing the hypothesis H ") can be adequately experienced only by trying to abstract from what our colleagues have "whispered" about their research objects and research projects. An experiment of this kind (performed by the author in 1938) consisted in noting down the overt behavior of a psychologist engaged (he said) in studies of anxiety in rats. The rat suddenly found itself on an unexplored open space and began running around. High frequency of defecation and long distances of (bewildered) running were taken as manifestations of anxiety. Adopting the position of (behaving as if) not knowing what the psychologist "had in mind," the metascientist placed himself "accidentally" in such a way that the rat could not be seen. He nevertheless succeeded in obtaining an "observational journal" very nearly isomorphic with that of the psychologist by listing his movements with head, eyes, and hands. This observational journal could be used, however, for an indefinite number of different hypotheses about the psychologist, one being that he was practicing certain rules for coordinating head and eye movements and writing down symbols for those movements in his protocol.

The lesson from this kind of "wildlife study"⁴ of researchers is that one must be extremely cautious about claiming that an assertion belongs to metascience if (as is here the case) it is thereby claimed that it belongs to a science *studying* science. Suppose the metascientist, uncritically, had introduced his account by stating that the psychologist A was "studying anxiety in rats." Suppose further that he was informed by A , ten years later, that

rats of course do not suffer anxiety, but only fright and that *A* therefore had not studied anxiety in rats ten years previously. The “metascientist” would then in a collegial way *change* his account, a sure sign of sameness of level.⁵

Maze Epistemology

The shortcomings of attempts to describe the scientific enterprise from the far outside in terms of research behavior can be shown to derive from one fatal flaw, that of “maze epistemology” (Naess 1936).

A psychologist constructs his mazes and assumes that his own description of them is the correct one. He introduces food or obstacles of various kinds and describes the movements of the rat, freely using references to his maze and the objects in it and postulating a drive and a goal; the rat is said to make correct or wrong turns, to be a fast or slow learner, to make true or false hypotheses, and to make good or bad cognitive maps of the maze.

What happens, though, if one of them tries to carry over the attitude of unquestioned superiority, or this absolute frame of reference of the experimenter, to the metascientist’s studies of the scientist? One notices at once that the metascientist does not, and cannot, make the mazes. What is the scientist looking for? Where are the goal, the culs-de-sac, the rewards? What is the problem situation? The metascientist must *ask* the scientist for information about the maze.

A description of science or the scientific enterprise may be said to be subject to the *error of maze epistemology* when the (would-be) metascientist announces his descriptions of the object of scientific research as the psychologist announces his description of his experimental setup—the maze, the food, the obstacles—whereas the descriptions are in fact more or less regurgitated information obtained directly from the scientist.

The error of maze epistemology results in the production of a quasi metascience, an ephemeral vision of science in terms of a part of the contemporary beliefs of scientists. In the interest of a genuine, if only fragmentary, behavioral view of the scientific enterprise, a step-by-step elimination of direct information by suitable methods should be carried out before claims are asserted that one has reached, in part or in approximation, a genuine metalevel.

The error is not only relevant to a description of contemporary science,

but also to historical accounts. It is known in that field as the “error of absolutism” in relation to the scientific beliefs of the historian’s contemporaries. Important chapters of the history of science have recently been rewritten by students of history who do not take the victor’s account (for example, Lavoisier’s) any more seriously than that of the defeated scientist (the phlogistonist’s).

Reformulation of the Program of Behavioral Science of Science

Concluding, we may characterize a practicable and consistent program of molar behavioral science of science as follows: it is a program of description and explanation of the scientific enterprise in terms of the scientist’s molar behavior units in the sense of doings, not motions, in research situations, using, as far as possible, the methodologies of behavioral science. The frame of reference of the descriptions, that is, of the observational journals, will *not* be independent of the conceptualization of a definite tradition or scientific culture. There will be no description of scientific practice in itself (*an sich*) as something invariable. A radical pluralism is thus called for.

The conclusion that participation is a necessary characteristic of the metascientist’s relation to the scientist and his enterprise is of special significance to psychologists, because their own relation to the subject matter of psychology, the human being, is of the same kind. This structure of participation might be further developed as a supplement to the less fundamental discussion on formal aspects of psychological methodology.

Behavioral Science, Logic of Science, and Philosophy of Science

The rise of psychology as an empirical science in the last decades of the nineteenth century inspired philosophers and scientists to advance theories *about* logic within the conceptual framework of a psychology of association, often combined with biological concepts of adjustment and achievement. These quite legitimate inquiries were, however, often marred by excursions into formal logical and methodological domains—an invasion that met little organized resistance before Frege and Husserl because of the lamenta-

bly low level of active logical research in those times. When this situation changed, reaction against “psychologism” set in with such tremendous force that not only were psychological conceptions swept out of logic, but a kind of witch hunt was carried far into the domain of general philosophy of science, a field in which many approaches are needed, and in which that of nonformal, nonnormative study must be fundamental in any delimitation of actual objects or processes studied. Thus, authors using terms that admit of both logical and nonlogical interpretations were criticized as if they *intended* to talk within the domain of logic, even if they did not. It is a stroke of irony that the antiempirical attitude has been strongest among philosophers who, in a broad way, belong to the empirical traditions in philosophy, whereas the philosophers more influenced by Neothomist, Marxist, phenomenological, or existentialist philosophy encourage systematic study of nonformal and nonlogical aspects of science.

The impact of symbolic logic and the renewed interest in logical problems quite generally, together with the perennially strong inclination of philosophers to rely on pure thinking rather than on masses of empirical material, has worked in the direction of identifying philosophy of science with “logic” of science. The term *logic* is used in more or less broad senses, the main emphasis, however, being on the philosophical irrelevance of actual happenings—for example, the way a term happens to be applied. A nonfactual program is explicitly stated by Karl Popper.

The deep effects of trying to take up a consistently logical rather than factual point of view is seen, for example, in Popper’s (1959) account of the empirical basis of science in his book on logic of science. A theory is (by definition) tested by basic statements. Certain stipulated logical or “formal” requirements for testing can be satisfied only by singular existential sentences. Therefore, theories are tested by singular existential sentences. Consequently, theories are, by definition and stipulation, such that we can derive the (admirable) falsifiability doctrine of Popper. What goes on is practically at all times *logic* of science—as we are justified in expecting from the title of the book (which is *The Logic of Scientific Discovery*). The question of observability is treated rather lightly, as are other “material” (Popper’s word) problems of immense nonlogical importance, problems that emerge when we ask, What *kinds* of singular existential sentences are to be classed as basic? Which are the kinds that have, *in fact*, been thus classed until now?

Popper complains—rightly, I think—of traditional confusion of logi-

cal with nonlogical aspects of problems and deplores the ill effects for logic of science. I myself regret the bad effects for the material, or nonlogical, aspects. It is, incidentally, to be expected that explicit, consistent treatment of the nonlogical aspects will make it easier for the logician to eliminate them. The recent history of the logic of science has shown how difficult is this elimination. Today there is a tendency to derive material conclusions from formal investigations just because modern logic has furnished explicit and scientific ways of handling formal problems, whereas material problems are largely dealt with intuitively or implicitly in the absence of any established nonlogical science of science.

The Case Against Science

The central topic of this paper is thirteen complaints or grievances formed in countercultural¹ environments and directed against science. Most of them are formulated in a way that suggests a general disapproval of the scientific enterprise. My main conclusion will be that they are on the whole well-founded insofar as they oppose dominant trends of science in the industrial states (including certain eastern European ones), but on less firm ground when they take issue with science in general.

There are two subordinate topics. The first is the antiscientific, antirationalist countercultural reaction to establishment science and to the way science is taught at the universities. This reaction sometimes takes forms verging on the comical, yet it is both healthy and important in its main concern, which is the narrowly intellectual and technical rationality of industrialized science. The second topic is the role of science in a society that exists in ecological equilibrium.

Eulogy: The Cheerful Face of Science

The term *science* evokes significantly varied reflections and emotions. I belong to the thousands of researchers who experience intensively positive associations. I am reminded of a search for Miocene carnivores in a California desert. We dug out bones of small horses and camels, having located a water hole near which they, millions of years ago, presumably gathered and

This article was reprinted with permission from *Science Between Culture and Counterculture*, edited by C. I. Dessaur (Nijmegen, Netherlands: Dekker & Van de Vegt, 1975), 25–48.

many of them died following an attack by carnivores. Where were the attackers, though? It was not easy to figure out where to dig for their bones.

This stay in the California desert, where we studied conditions of mammalian life twelve to fifteen million years ago, was entirely meaningful. Neither the midday heat nor the scorpions could lessen our joy. The tools were cheap, and agricultural districts in the vicinity enabled us to live in ecological balance. Thus was science established as a main ingredient in an entirely satisfactory way of life.

The extensive generalizations of textbooks concerning Miocene horses do not, of course, reveal any of the joyful aspects of research. I quote: "The Miocene saw the horse family flourish to a greater extent than did any other period. It began with one lone genus, *Miohippus*, which soon branched into *Kalobatippus*, *Hypohippus*, *Anchitherium*, and *Parahippus*. In its turn *Parahippus* gave rise to *Meryhippus*, which branched into *Protohippus*, *Hipparion*, and *Pliohippus*" (Loomis 1926: 134–35).

Unhappily, science is often more or less identified with texts written in strange jargon. The preparation of such texts is an important part of the scientific enterprise, but to make people who yearn for science as a way of life memorize them may soon be regarded as one of the barbarisms of our century.

In what follows I shall accuse dominant trends of modern industrialized science of a number of crimes. However, my charges do not touch upon science as it can and should be.

My enthusiasm for science in general is gone. Like thousands of others, I have come to see the dark side of the scientific enterprise. My enthusiasm for research as a way of life is still there, but that kind of life has become a rarity in industrial societies and is not characteristic of what science as a gigantic enterprise does to society and to that major portion of youth who never experience research as a main ingredient in a meaningful way of life.²

Dyslogy: The Sad Face of Science

A short semantical note is now called for. The term *science* is used in many senses. One authoritative use defines "a science" as "a coherent system of more or less general propositions systematically supported by evidence obtained through the use of particular methods that have an interpersonal

and intercultural status.” The propositions of such a system are said to express scientific knowledge and are thought of as having a high degree of certainty, though they are not necessarily either plainly or eternally true. Scientific propositions are rather thought of as eminently testable and falsifiable. The body of scientific knowledge is considered to be accumulative.

Studies of science in this comparatively narrow sense are now often said to concern the internal relations of science, but “science” is also used in the very different sense of the total scientific enterprise. As such, it has been undertaken on a vast scale only recently. In industrial societies science has become gigantic in scope—bureaucratic, impersonal, and politically powerful.

In what follows we will be exclusively concerned with science in the latter sense. Studies of science understood as the scientific enterprise are said to be studies of the external relations of science. Obviously, however, the internal relations presuppose the external ones, and vice versa.

We shall see how criticism of the external relations also affects the internal relations. Thus, as scientists we cannot remain aloof from the vigorous protest movement at the universities and in society in general.

Science has a gay and angelic as well as a sad or diabolic profile. The latter shows itself when we consider certain well-founded grievances against science.

Grievances Against Science

Science and the Powers That Be

Since research is part of the quest for truth, the scientific community has been widely expected to take a vigorous stand against people in power who manifestly propagate untruth. Twentieth-century opposition to pseudoscience, for example, was partly led by scientists, among them inmates of concentration camps. Wherever people in power have directly interfered in matters of scientific concern, some scientists have protested and others have at least supported the protesters.

Yet in cases of false accusation, distortion of contemporary history, and false propaganda in general, it is said that scientists by and large keep away from the conflict. Authors, artists, and other groups are said to be more alert, whereas scientists try not to antagonize sources of funds, equipment,

or campus facilities. The scientific community did, for example, acquiesce in Hitler's transformation of the universities, and in modern dictatorships scientists are said to keep quiet provided they are handsomely rewarded. The sad truth is that a scientific career is not conducive to civil courage.

Science Serves the State

Especially in the United States there is a widespread reaction to defense research being done at universities with the tacit approval of the vast majority of scientists. The Vietnam War showed first-rate physicists and biologists at work inventing devilish new weapons of war. Moreover, this was condoned by the research community at large.

In general, it seems that any kind of regime and any kind of project, including scientific methods of torture, are more or less condoned by the majority of scientists in the sense that they do not join fights against these things. They organize neatly, at least in some European countries, as pressure groups for higher pay and so on. They belong to unions. Their lawyers fight hard to safeguard their clients' material and other privileges.

There is mounting pressure in the West to make science the servant of centralized governments. The still fairly high degree of autonomy in selecting research topics is being challenged. "Science . . . can no longer hope to exist . . . , through some mystique, without constraints or scrutiny, in terms of national goals, and isolated from the competition for allocation of resources which are finite" (Ivar Bennett, deputy director of the Office of Science and Technology, 1966, quoted in Greenberg 1967).

The cost of modern science and of a university education is tremendous, and it is only fair that government officials and the public should try to impose restraints. It would, however, be much better for society and for the individual researcher if the scientific community showed wisdom and self-restraint and turned to a philosophically and ecologically justifiable way of life.

Elitism and Privileges

There is a pyramid of prestige, pay, and privileges in the universities and research institutions. Careerism is rampant and often there is a pervasive at-

mosphere of competition. Science has created big and ugly pyramids of power. In Eastern Europe scientists who are willing to serve the government and to keep quiet constitute a new “aristocracy.”

The industrial states encourage an all-against-all race for well-paid positions with high status. A scientific career offers just this. The state tries to discover talent by testing and screening. Successful candidates are offered pay and privileges that set them apart from the majority of people.

Marx said about one hundred years ago that the Anglican church would rather forgive an attack on thirty-nine of its articles of faith than on one thirty-ninth of its money income (*Capital*, foreword). Science at that time could perhaps not be compared to a church, but its material wealth and the affluence of its “bishops” may cause it to resist social reforms in a manner that resembles that of the European churches in Marx’s time.

The Pilate Reaction to Criticism

I shall now consider one of the most serious charges leveled against science: its moral indifference. It is said that the scientist cannot be blamed for the extensive misuse of scientific results. “[D]ecisions about the use or abuse of scientific discoveries are made by politicians, ultimately by the elected or appointed representatives of society; they are not made by scientists” (H. J. Eysenck 1954). It is also said that the scientist has neither the means to predict how his results will be used nor the capacity eventually to find out how they have been used. What sudden modesty!

In many cases scientists do have the capacity—but not the will—to investigate the uses made of their discoveries. In other cases, especially in purely theoretical fields, there is no way of ascertaining what will be the consequences in the long or even the short run.

A few scientists have discontinued theoretical research because of suspected misuse of their findings. An example is James Shapiro, the Harvard biologist, who said some years ago: “In and of itself our work is morally neutral. . . . But we are working in the United States in the year 1969. . . . These people [in power] have consistently exploited science for harmful purposes.”

In many countries there are organizations that help scientists who are “conscientious objectors,” that is, those who leave their jobs rather than

work on dubious research projects. In the United States one of these is the Society for Responsibility in Science, which has branches in Europe.

Support of Technocracy

The close relationship between technological and scientific development in the West finds expression in technological thinking on the part of scientists. There is, for example, a widespread belief in technical solutions for social problems. Although the slogan “social engineering,” which was common among social scientists in the 1930s, is no longer in use, the idea lives on.

In many countries—of which Norway is one—governments increasingly take action on the basis of recommendations from technical agencies. One of these agencies calculates what is misleadingly called the increasing need for energy. The term *need* sounds so human, but the scientific calculation and extrapolation do not reflect human needs; they measure the effective demand on the world market, effective demand being defined as one that is backed by money. The Norwegian government acts upon the scientific conclusion concerning the tremendous increase in our need for energy in 1980, 1990, the year 2000, and so on, and decides to engage in vast oil adventures along our coast and to destroy rivers and landscapes in order to produce electricity. Politicians lack the means to work out alternative policies, since behind the recommendations of technologists may be months or years of scientific work, costing millions.

The countercultures vigorously protest against the unholy alliance of scientific personnel and institutions of modern technoculture. Their advice is to “get out,” and indeed many gifted young men have given up their technical or scientific careers.

Where a technological outlook prevails in the social sciences, we find rationalizations of societal arrangements reminiscent of Huxley’s *Brave New World*. In the 1930s and 1940s prominent social scientists predicted that politics would be replaced by science-based decision making, with a technocracy functioning as executive branch.

The utopia of scientific politics is largely dead, but opinions derived from it are very much alive. According to one contemporary believer in scientific politics, Daniel Moynihan, the social sciences “will give govern-

ment an enlarged capacity to comprehend, predict and direct social events” (1975). Considering the general quality of governments, such increased centralization is highly undesirable.

What is desirable is that people, not governments, obtain an enlarged capacity to comprehend, predict, and direct social events. That is, it is desirable that people direct themselves rather than be directed.

As the term suggests, a technocracy is a society that stresses the development of means for their own sake, while neglecting goals. Means, such as transportation, energy, organization, engineering, administration, and planning, are developed uncritically. The cultivation of values is not taken seriously. Nor are reflection and an autonomous lifestyle encouraged.

Again, our ultimate conclusion cannot go against science as such, because our criticism concerns only a dominant trend in science. Increasingly, the opposition to technocracy is strengthened by research started or instigated by individuals belonging to one of the countercultures.

Neither natural science nor the social sciences are inherently conducive to excessive technical development. What is known as scientific neutrality is not itself a scientific thesis but part of an antiphilosophical philosophy. The excesses stem from cultural and economic trends that can be explained only on a broad historical basis. Without science, the modern technocracies and their devastation of nature could not have developed, but it does not follow that a general downscaling of the scientific enterprise will result in diminished technical dominance.

Some parts of the scientific enterprise clearly need to be expanded. Think, for example, of the new trend in economics that stresses social cost rather than monetary cost. There are also studies of economic systems based on non-Western value scales. Thus, a Buddhist economics has been developed in Burma.³

Manipulation

In Western societies, industry makes use of vast scientific resources in order to sell its products.

The use of psychology and other sciences for the manipulation of tastes and ways of life has increasingly come under fire. Critics have noted that even the definition of certain sciences suggests their manipulation and

degradation of the individual and society. The theoretical goal of psychology, says H. J. Eysenck, "is the prediction and control of behavior" (1954). Such control may be invisible; that is, the populace may be scientifically controlled in its behavior without having any clear idea of what is happening. Hannah Arendt concludes: "The trouble with modern theories of behaviorism . . . is that they actually are the best conceptualization of certain obvious trends in modern society" (1973).

This indictment concerns certain trends, not psychology as such. The widely used book *On Becoming a Person*, by C. R. Rogers and hundreds of other books show how important trends in the behavioral sciences join hands with the counterculture to reduce manipulation.

Many people generalize their criticism of manipulatory scientific projects into an indictment of the role of science in industrial society. Yet certain behavioral studies today aim at reducing interference and manipulation. I have in mind the vastly expanding field of the ecological study of animal (including human) behavior. The general conclusion of these studies amounts to a warning that we know too little about the long-range effects of the interference with and manipulation of nature to be justified in continuing them.

Lack of Respect for Personal Dignity

Certain trends in modern behavioristic psychology have been taken as symptoms of a lack of respect for personal dignity. The most notable representative of such trends is B. F. Skinner, who openly favors a technology of behavior. One can, according to this prophet, change human behavior without too much understanding of how it has come to be as it is, or how people experience their own selves, freedom, decisions, and goals. "[W]e do not need to discover what . . . plan, purposes, intentions really are . . ." (Skinner 1971: 15).

Already, very tough kinds of so-called behavioral therapy exist. It was discovered in Norway that behavioral scientists systematically use isolation to change the behavior of a child. In the subsequent public uproar, science and expertise were often seen as the cruel, inhuman agent.

Drug addicts have been treated with a drug that produces paralysis and agonizing suffocation. The doctor whispers to the immobilized patient

frightful accounts of the dangers of narcotics. In another kind of experiment, the big spider known as a tarantula proved to be a most effective horror in aversion “therapy.”

The ecological movement fights for the rights of animals. A vast number of research projects use animals in painful experiments. One kind of justification will no longer hold: that of merely advancing human knowledge. Nor is it enough to point vaguely to a possible use in medicine and related sciences.

The policy of universities should be to minimize cruelty through self-control, and not wait to change things until outside pressures build up.

Pretense of Political Neutrality

If what is said in previous sections is true, then the scientific enterprise is not a neutral power in relation to contemporary political and social movements. Not telling the truth to the powers that be has the effect of backing the regime in power, whatever its merits or faults. The acceptance of projects such as Camelot (See I. L. Horowitz 1967)⁴ and many others in the social sciences reveals an interest in the perpetuation of existing power structures. The acceptance of special privileges makes it tempting to go along with the regime that defends those privileges. The support of technocracy is not politically neutral but serves industrial interests and producer interests in general, rather than low-income consumers.

Whereas equations, whether in mathematics or ecology, do not have political meaning, the choice of favorite fields for costly research is in part politically motivated.

In spite of these obvious relations between politics and science, there is a persistent claim of political neutrality, or the claim that science is democracy’s best friend (Sir K. R. Popper). The historian of science Joseph Needham proclaims that democracy might “almost in a sense be termed that practice of which science is the theory” (1949).

Open-mindedness and disinterested registration of facts have been thought of as supporters of democracy. Even a great scientist, however, may well be ignorant and dogmatic in all matters outside his specialty. His contact with people at large may be very superficial.

It must be conceded, though, that heavy-handed interference by politi-

cal commissars in scientific discussion is a condition that many scientists are willing to fight against, even at the risk of imprisonment and death (see, e.g., Medvedev 1969 on the Lysenko affair).

Autotelism, Intellectualism

Does scientific knowledge have intrinsic value? Is knowledge to be sought for its own sake?

In my view it is never knowledge that has intrinsic value: only increased understanding does. The value refers to a subject that understands, given a finite capacity and available time. Understanding is personal; knowledge is impersonal.

For Roszak and many others of the counterculture, science as such has an inherent norm that says that knowledge is to be sought for its own sake “as a thing apart from compassion, humanity, wisdom, beauty” (Medvedev 1969: 253).

Against this it must be said that if science as a set of propositions or as a methodology is abstracted from the human scientific enterprise, it cannot contain its own recommendation. There will then be no norms saying that somebody should use the methodology without regard for wisdom or any other intrinsic value. On the other hand, if science is taken in the sense of the total human scientific enterprise, the norms of methodology are only one set of norms among others. Any action will have to be judged in the light of priorities. Thus, the complaint of lack of wisdom or compassion cannot be a general complaint in order to be justified. It only concerns particular actions or projects.

It is said that science has become more dependent on costly machinery, but this observation mainly reflects the needs of industrial states. There is nothing inherent in scientific methods, whether in the natural or the social sciences, that in an absolute way requires costly machinery. All depends on priorities of fields of research.

There is a minority of a few thousand people who do competent research without any public support whatsoever. They have some kind of job in order to obtain the necessities of life but spend most of their time in research. Their use of costly machinery is very limited and could be still less in a somewhat different society. Our conclusion is a counterattack: why do

not more people in the counterculture turn to research? It might make their life richer and more meaningful. Many teachers inside and outside our universities would certainly be glad to help them on their way.

It is a valid complaint that the scientific enterprise today includes a vast number of projects that add to our knowledge, but quite irrelevantly. It is also an impersonal affair in the sense of boring attempts to obtain a degree or a position. No personal or public interest is involved.

Again, this cannot be a completely general complaint, and we all agree that it is extremely difficult to find persons or committees who deserve to be entrusted with the power to determine whether the kind of knowledge or understanding aimed at in particular projects is worth having. More wisdom is required in the research communities. More self-respect, more joy.

Science Does Not Serve the People

Marxists constitute the most important and powerful group attacking the scientific enterprise as it functions in Western societies, including Eastern Europe. They are basically antirevisionist, attacking Soviet science as vehemently as they attack that of the United States and the Common Market countries.

In general, these groups contend that the scientific enterprise, at least as it functions now, does not serve the people. I would say: "does not serve the underprivileged." Nationally it serves the exploiters, and internationally it exploits the Third World. This is evident from the fact that the scientific enterprise supports capitalism and social imperialism, and that neither of these serves the people. Science as it functions today is largely an instrument of domination. Its ideal is knowledge of the kind that supports any establishment, and hence the status quo.

Science, say the Marxists, should serve the needs of the masses rather than improve upon gadgets and services that are beyond the means of the less privileged. Medical research should concentrate on how to improve public health and not waste millions on special cures and operations that can only serve a small privileged minority.

Research in general should concentrate on the urgent problems of developing nations rather than spend vast sums on improving material conditions in affluent countries.

Under the influence of trends in China, there is also a tentative widening of the definition of research so that not just members of an elite with very special formal education can be scientists.

The “Serve the people!” movement may consistently oppose nearly every research policy at European universities without turning against science as such.

*The Limitations of Scientific Rationality and the Depreciation
of Non-Western Cultures*

To what extent do countercultural groups through “the rising antirationalism” threaten the prevailing philosophy of science—let us call it P_1 —and the university as we in the West have always known it?

There is, I believe, very little threat to Western universities from a philosophy of science different from P_1 —but what if we add certain values to P_1 : open-mindedness, tolerance, respect for the autonomy of the creative scientists? Let us call this more comprehensive philosophy P_2 .

Large countercultural groups do not think these values are upheld in Western science, and to a significant degree recent historiography is on their side. Since the Renaissance the great universities have functioned mostly as strongholds of reaction and dogmatism. The “free” universities of Germany before the world wars were authoritarian, and the opinions of the professor *ordinarius* more or less sacred. Research followed definite patterns, which were not chosen through a sovereign scientific rationality but were largely determined by general historical forces and the dominance of particular metaphysical views. I can here refer to works by I. Agassi, J. D. Bernal, H. Butterfield, P. K. Feyerabend, T. S. Kuhn, I. Lakatos, and M. Polanyi.

For the purpose of this paper, the most important conclusion is that there is no independent scientific rationality. Only total views, such as that of Spinoza, are comprehensive enough to comprise norms of rationality of lasting worth.

To return to P_2 , it seems that reforms of universities and of certain dominant patterns of research in the industrial states may well create conditions favorable to the realization of such a philosophy.

So much for rationality. Prevailing attitudes in many scientific communities attest to a rather narrow conception of what is rational—border-

ing on the merely efficient and the conventional. One subcultural complaint concerns the evaluation of non-Western cultures.

It is easy to find scientists who look down upon so-called primitive cultures. They cherish the belief that scientific rationality is an autonomous rationality requiring no philosophical or metaphysical framework. A kind of summary of textbook science is believed to furnish a scientific worldview.

An astonishing example is picked out by Roszak. He quotes Kroeber's *Anthropology*, page 298, where it is said that deviations from "scientific rationality" are chiefly found "among individuals whose social fortune is backward or who are psychotic, mentally deteriorated, or otherwise subnormal."

However, it is just as easy to quote scientists who express admiration of other cultures.

Since World War II, new branches of economics have developed that take the value priorities of developing countries as a basis for research. It is instructive to see how policies that are judged to be rational in Western industrial states are condemned as irrational within the framework of the new economics. In our industrial societies "a man who consumes more is 'better off' than a man who consumes less. A Buddhist economist would consider this approach excessively irrational: since consumption is merely a means to human well-being, the aim should be to obtain the maximum of well-being with the minimum of consumption" (E. F. Schumacher, in Daly 1973: 123–24).

Again, it is seen that while our science-inspired culture is extremely weak in some respects, it is healthier than ever in others. Far from despising other cultures, ecologists and social anthropologists often express great admiration for both primitive human and animal societies. If we were to list the twenty most pressing social problems and ask social anthropologists which of them are most successfully solved in which cultures, our industrial countries would not score high. Thus, we find scientists among our best-qualified cultural critics.

Reductionism and Positivism

We now come to one of the most interesting criticisms of science itself.

Roszak defines reductionism as the attitude "which degrades what it studies by depriving its subject of charm, autonomy, dignity, mystery. . . .

As Kathleen Raine puts it, it is the mentality which would have us see in the pearl nothing but a disease of the oyster" (Roszak 1972: 264).

It should be unnecessary to stress that the scientific study of pearls need not imply lack of appreciation, but the publication of the results of such a study is rarely the right place to express that appreciation. Moreover, only scientists can properly assess the marvelous processes by which the oyster produces a pearl, and, so far as I know, usually it is only scientists who identify with oysters deeply enough to feel regret when an oyster is hurt.

It seems to me that Roszak, like so many others, confuses science with the learning of scientific results. Roszak's criticism does not concern research but its degradation. However, there are far more philosophical arguments concerning inherent scientific reductionism. Science explains, that is, often *reduces*, the mysterious and wonderful to the understandable. "[I]ts goal is the destruction of mystery" (B. F. Skinner 1971). Any scientific explanation is partial, however, and even if it were not, mystery and wonder may remain or even increase. Chemical and optical explanations of the luster of pearls or of the processes occurring in the oyster may elicit more wonder than isolated aesthetic appreciation. The advances in biochemistry make living matter yearly more fantastic and more unbelievably ingenious, but I see no reason why scientific journals should contain artistic expressions of the deep appreciation of the subject matter. Why compete with the poets? They have enough problems as it is.

Another charge of reductionism concerns the perversion of simplicity as a fundamental requirement in scientific theory, such perversion leading to a systematic reduction of subject matter in the study of complex phenomena such as the human personality. This objection is clearly valid when theories of personality are put forth with undue pretensions, as unhappily they often are.

Simplicity may be one of the main scientific reasons for theories that make the Earth circle the sun, and not vice versa. Among competing theories of the movement of bodies in the solar system, scientific methodology urges one to adopt the theory that explains the most through the simplest means. Now the solar system is very complex. Therefore, the simplest adequate theory is highly complicated. Thus, the simplicity rule does not forbid us to recognize complexity. Reductionism, therefore, is not a consequence of the simplicity rule.

The complaint of reductionism is intimately connected with the nearly universal charge of “positivism!” The meanings of this term vary widely, but very often it stands for *lack of reflection*. The positivist scientist, it is said, does not reflect on what he personally is doing or what his group or class is doing, what his presuppositions are, and in which historical situation he is an actor. The antipositivist movement is pro-philosophical and pro-politics, decrying the lack of autonomy on the part of scientists.

“[T]o desert scientific culture in disgust at its incorrigible reductionism” (Roszak 1972: 232) reveals philosophic misguidedness or sad defeatism.

Nature as the Object of Science

In the last fifteen years extensive studies have been prompted by the question of how Western man could have developed such crude and cruel ideas about his place in nature. How has it been possible to ruin so much of nature without strong opposition from nature’s professional students? Why have some natural scientists since Galileo and Bacon been the leading proponents of the notion that nature is there to be subdued and exploited for narrow purposes, economic and otherwise?

Some have answered that it is largely owing to the prevailing scientific worldview, and the special character of natural science.

Hypothetico-deductive methodology has been singled out for special criticism. From general laws plus initial-condition statements, “predictions” are derived. Theories, it is said, are instruments for the control of phenomena through this function of prediction. The function of laws is mainly to fix the established order, to freeze existing conditions. This is clearly seen, it is said, when the social sciences imitate hypothetico-deductive methodology—as they do in technocracies.

However, the term *prediction* in hypothetico-deductive methodology is a name for directly testable sentences derived from initial-condition statements. They do not necessarily, or even mainly, predict future phenomena of interest. Nor is the tremendous stress on testability to be confused with emphasis on the control of the phenomena. The most admired hypothetico-deductive systems, such as the kinetic theory of gases, are clear examples of models, that is, of a very abstract kind of map of phenomena. The confusion

of map and terrain shows lack of real understanding of natural-science methodology.

“The world is *really* made up of atoms and the void.” Clearly, there is a tendency to take fundamental natural-science models to be straightforward descriptions of the real world. The theory of primary qualities still has its adherents. Some still hold that colors do not exist in nature but are somehow made up in our brains. Thus, there are dominant trends in the scientific community that reduce nature to a vast chaos of waves and particles without properties: no colors, no tones, no definite forms, no recognizable qualities at all.

Such a nightmarish nature, of course, only deserves to be exploited and subdued.

A deeper study of natural science (including ecology) leads us, I think, to a much wider view of its methodology. There is not one but a number of methods in natural science. Careful study also frees us from believing that there is such a thing as a definite scientific worldview. All worldviews must go deeper than scientific disciplines; that is, they must include ontology, logic, and of course general methodology, which itself cannot be “scientific” in the sense of being subject to verification.

There is a tendency to imitate natural science in the contemporary study of society. Here again, there is room for very substantial criticism. The Frankfurt School has in eminent ways attacked the technocratic aspects of the social sciences and government-sponsored expertise, both of which play an increasingly powerful role in policy formation. However, its characterization of natural science is not tenable. There is no inherent tendency to manipulation and control in the hypothetico-deductive and other methods employed by natural science.

Concluding this section, we might return to one of its introductory questions—why natural scientists have helped destroy and exploit nature. Evidently, an important minority has been doing exactly the opposite—the naturalists. Enthusiastic botanists and zoologists have since the time of Aristotle fought the haughtiness and insensitivity of man. Paleontologists have always tried to make mineral exploiters and others take care not to ruin fossil beds. It is an irony of the history of ideas that countercultural authors have adopted the technocratic view of natural science or the textbook view, which suggests that “flowers hate botany.” If so, why should not

flower-power hate science? The premise is false: the counterculture could learn a lot from natural scientists.

The Cult of Nonscience

Mainly as a reaction to the hollow pretenses of the scientific worldview, whatever is conventionally judged to be unscientific tends to be wildly popular with academic youth. Young graduates and postgraduates, some of them in responsible positions, find satisfaction in all sorts of magic, in mythologies both ancient and modern, and in ways of life consciously violating scientific rationality. Any genuine human rationality is nonscientific, and to reject the so-called scientific worldview is perhaps one of the most rational things to do today.

Recently, the worldview revealed through hallucinatory drugs, as well as the sorcery and black magic of the Yaqui Indian “Don Juan”—as revealed in the three excellent books by Carlos Castañeda—has been widely praised. For many people with a university education, the world picture of black magic seems much closer to reality than that of modern physics, behavioral psychology, and other sciences. I think these protesters may be right. What is regrettable is that they seem to consider only two alternatives, a wild scientific worldview or a wildly magical one, abandoning the main philosophical traditions of both West and East. We should ask ourselves, Do our generalizations about the modern scientific enterprise do justice also to the research done in social anthropology and many other new areas? These are genuinely parts of the total enterprise and must be considered in any adequate assessment of the present and future function of science.

The cult of the nonscience provokes firm believers in scientific rationality, whose hollowness is revealed by their fierce reaction. An act is rational only if it conforms to a consistent set of ultimate valuations. Even to defend one's life is rational only when certain norms are accepted as valid.

Nor must politics be left out. The Marxist movement and subculture have taught us to analyze present-day power constellations and not to neglect the political fight necessary to establish a rationality of a more meaningful kind than is realized today in our industrial societies.

The eminent philosopher of science Paul Feyerabend attacks the self-glorifying ideology of scientists. They do not admit their dependence on nonscience and even the unscientific. “‘Unscientific’ procedures such as the herbal lore of witches and cunning men, the astronomy of mystics, the treatment of the ill in primitive societies *are* [said to be] totally without merit.”⁵ Copernicus took over the idea of the “muddleheaded” mystic Philolaos, whose view was called incredibly ridiculous by professional astronomers such as Ptolemy. “Even today science can and does profit from an admixture of unscientific ingredients. An example is the revival of traditional medicine in communist China. When the Communists in the fifties forced hospitals and medical schools to teach the ideas and the methods contained in the *Yellow Emperor’s Textbook of Internal Medicine*, and to use them in the treatment of patients, many western experts predicted the downfall of Chinese medicine. What happened was the exact opposite. Acupuncture, moxibustion . . .” (Feyerabend 1975a)

Feyerabend has things to say about the social role of science that may gladden the heart of many friends of countercultures:

“Let us free society from the strangling hold of an ideologically petrified science just as our ancestors freed *us* from the stranglehold of religion!” Why should the ideology of science be compulsory in schools? “Physics, astronomy, history *must* be learned. They cannot be replaced by magic, astrology, or by the study of legends.” Feyerabend sees this as an inconsistency: if parents can decide whether a six-year-old child should be instructed in Protestantism or in the Jewish faith, why can they not decide whether the child should be instructed in the rudiments of scientific faiths? The governments should treat science as the United States treats religions. This means that financial support for science should “be drastically reduced.”

Again, the complaint against science is well-founded and needs to be taken seriously, but it does not touch science as such.

A last general remark on nonscience:

Because of the intellectually and epistemologically fragmentary character of individual disciplines and even of the total set of sciences at any time, a comprehensive or near-comprehensive view cannot be scientific. It follows that all consistent comprehensive views have an equal claim to validity—and none is scientific.

Science in a Community in Ecological Equilibrium

What is called the deep ecological movement has a number of main tenets.⁶ First, there is the pollution issue. The pollution caused directly or indirectly by the scientific enterprise is well known. Resource depletion is a second issue. The great consumption of energy and other resources through lopsided scientific development is under attack.

International science is hierarchical and centralized, with a built-in tendency to bypass research aimed at solving local problems. Ecological equilibrium requires intensive development of local research as well as decentralization. Self-sufficiency, not only in the material sense but also in educational opportunities, is a goal that can be rapidly attained if research is concentrated in these fields. Thus, the third and fourth aims of the ecological movement also call for a redirection of science.

A society in ecological equilibrium will probably have to eliminate many privileges. Even at the expense of professional efficiency, students and staff may have to partake in primary production. It is expected that this will also have a beneficial effect upon the prevailing ideology. It may further the basic ecological aim of making life complex rather than complicated, that is, of developing all faculties and opportunities, living in a rich local environment requiring many and varied kinds of activity, and on the whole obliterating the strict separation of work and leisure.

All in all, the deep ecological movement tends to give greater priority to action research—relatively short-term, goal-directed, informal investigations directed toward solving practical problems on the way toward ecological equilibrium. Because of the prevalent methodological primitiveness, high officials in universities and research institutions tend to scoff at such research problems. It is easier to get money for projects using sophisticated machinery and furthering what is now called eternalist science—science resulting in propositions of lasting value and general interest. The local problems of survival—physically and spiritually—are mostly not of this kind.

Why Not Science for Anarchists Too?

Das war eine grausame Salbe! I suspect that this or some similar exclamation will spring to the lips of many readers of Paul Feyerabend's essay and "Theses."¹ At the risk of being judged pedantic and completely lacking in humor, I should like to take the opportunity to sort out and comment upon a selection of norms and hypotheses suggested in the two pieces.

External Relations of Science Underrated?

It is true that the study of science's internal relations, such as the mutual implications of hypotheses, or the influence of one theory upon the acceptance of another, has been carried out with more energy, and has (perhaps) been more willingly supported by the research administrations of English-speaking countries, than the study of external relations. These latter are primarily the relations of the scientific enterprise (including the scientific communities or scientific social systems) to society in general, including all social systems, national and international. However, since the meeting of the International Congress of the History of Science and Technology in London in 1931—with ample Soviet Marxist participation—and more specifically, since the triumph of military science in World War II, the external relations of science have been increasingly studied, and, what is more important, studied critically as part of a political and economic establishment. The reader is invited to inspect the short appendix at the end of this paper.

This article was reprinted with permission from *Inquiry: An Interdisciplinary Journal of Philosophy* (New York and London: Routledge, Taylor & Francis Group) 18 (1975): 183–94. It was originally published as a reply to Feyerabend.

One central theme in this connection has been the function of science within so-called advanced technical-industrial societies (the United States, the Soviet Union, and the European Economic Community, in particular).

It is a main thesis of Johan Galtung, for example, in his *Methodology and Ideology* (1977), that there is a clear and detailed isomorphism between rules of scientific methodology and ideological posture. There is ample evidence for this—though of course the correlation between Galtung's own methodology and posture also needs clarification.

Grievances Against Science as Part of the Advanced Industrial State

A great number of grievances against uncritical acceptance among scientists of the aims and institutions of the advanced technological societies have been formulated and are under discussion.

Paul Feyerabend's papers offer valuable formulations within this debate. In schools and universities, science is still largely taught as if it were an ahistorical phenomenon. As teachers we are all more or less responsible for the deplorable effects of this, and should support those who work for change so that future students "will study science as an historical phenomenon *and not* as the one and only sensible way of approaching a problem" (Feyerabend 1967: 175).

Feyerabend proposes that schools give equal opportunity to magical and other ways of approaching a problem, and that none should be obligatory (ibid., pp. 175–76). Excellent—at least insofar as there is a widespread illusion to combat.

The Illusion of a Scientific Philosophy

The use of formal-logical, mathematical, psychological, and other limited scientific and nonscientific techniques within a broad debate on philosophical issues has, I think, contributed positively in the historical development of research. At the same time, though, a "positivist" and "reductionist" tradition has developed that takes Western scientific techniques and conceptual frameworks too seriously and scorns anything else, especially metaphysical, religious, artistic approaches. Conceptions of "scientific rationality"

have been promoted that are narrow, intellectualistic, and provincial, taking Western natural science since Galileo as the sole paradigm.

The technically advanced conceptual frameworks used in philosophical debate are sometimes taken to constitute the whole of philosophy. There will naturally be a reaction against this, and Feyerabend helps to bring it about.

Science Not Considered Neutral

Feyerabend claims that science is not neutral or without prejudice but is “an historical phenomenon” (ibid., pp. 169, 175). Yes, and hermeneutics, the Frankfurt School, and much Anglo-American sociology of knowledge have all contributed to the detailed picture of science as a historical, political, and ideological phenomenon. These aspects of science have been studied with such intensity that sometimes the internal relations of science have disappeared from view. This accounts for the widespread acclamation of Hans Albert and others who support various forms of Popperian rationalism in the ocean of continental European “antipositivism.”

New Lifestyles: For an Elite or for the Many?

The Role of Research

The cultivation of spontaneity, creativity, nonparticipation in the rat race, downgrading of grading and of formal education—all this plays a part in new lifestyles. To whom, though, are these lifestyles open?

Somewhat different attitudes toward science are required depending on whether the new anarchistic lifestyles—in beautiful natural surroundings and concentrated around essential life needs—are supposed to be open to many people or only to a few, a small elite, as is the case now. Further, the fortunate elite has to consider whether it is going to try to help the less fortunate. In what follows I presuppose that a new lifestyle is going to be possible for many and therefore requires political action within the existing framework of so-called advanced industrial societies. As will become clear, I hope, we shall have to support many kinds of research, some strictly scientific, others rather sloppy, and to join in the opposition to others. Insofar as making programs goes against Feyerabend’s philosophy, this of course violates his principles.

Science for Subcultures

Today's nonviolent anarchists and nonanarchists try to maintain old-fashioned, or develop new, forms of community, adopting lifestyles different from and in opposition to the dominant ones. The emerging subcultures have members and supporters among scientists. With their high status and access to people in power, the latter are sometimes able to contribute to the defense of the new communities, for example, by preventing their erasure through administrative action. There are also lines of research that are directly influential in defending such communities, for example, those that furnish arguments against the further undermining of small communities. Besides the typical establishment-supporting science, there is also science helping the minorities who wish to find their way out of the present impasse in the technical-industrial societies. Maybe the help is little, all too little, but one should not fight science in general if this means destroying a source of support for, say, nonviolent anarchists.

Underestimation of Nonscientific Knowledge

From the history of research we know that insight among people without "scientific" background and training is often superior to that of highly trained scientists. Thus, when experts are asked about the environmental consequences of certain building ("development") projects along the coast, local fishermen can often furnish more relevant data and theories than the scientists ever could. In other cases, scientific projects costing enormous sums of money, at least from the point of view of the local people in developing countries, produce only a couple of insights that to them have long been commonplace. Feyerabend is, I think, completely justified in combating the overestimation of insights gained through methodologically "correct" procedures, and in combating the illusion that scientific theories are inferred by some kind of inductive logic from indisputable data. This overestimation is not, however, a general attitude, and one of the ways of combating overestimation is to teach better, more critical philosophy of science, especially history, sociology, and politics of science in a philosophical perspective. This means not less, but more relevant science! Feyerabend is right, too, I think, in asking for less concentration on science in education. Here there is a genuine problem.

Teachers are educated so as to feel competent only when distributing general knowledge—and the “best” knowledge tends to be conceived as scientific. Defense of other kinds of knowledge requires more courage and stamina.

Small-Scale, Soft, Action-Oriented Science

A substantial part of research has modest pretensions as regards methodology. If an investigation is carried out a little more systematically, with somewhat more explicit assumptions, and attention paid to some extent to what has been done by others in the field, it is called science. Consider, for example, a social psychologist testing the hypothesis that children on their way to school are careless in traffic. She does so by drawing up some statistics on where there have been accidents, and finds that some places show far more accidents and that those places have certain things in common. So to some extent she disconfirms the original hypothesis of carelessness and supports the hypothesis that it is the road engineers who have been careless. She recommends radical changes in the way traffic is handled.

What Do All Kinds of Science and Research Have in Common?

The above example is perhaps too crude a rendering of the particular “action research” I have in mind, but the main point is this: in general, research is only everyday finding-out done somewhat more thoroughly, reported somewhat more accurately, and with a little more stress on testability.

Approximately the same conclusion is valid if we look for common characteristics in research done in extremely different cultures. We must then accommodate Pānini’s grammar, Ramanujan mathematics (which lacks proofs), Egyptian geometry, and so on.

Science Helps Us to Learn About Nonscientific Cultures

“Galileo played the practical knowledge and general philosophy of craftsmen and artists off against the theoretical knowledge of the schools, and thus furthered mechanics” (Feyerabend 1967: 172). Something similar happens today. Research of the most diverse kinds—from medicine to military science—can learn from practitioners, magical and others. Moreover, action

research is a central slogan in applied social science, which is highly influenced by people who have jobs outside academic circles, such as social workers. In China a broader conception of science than that of the West is being evolved. Its program is to mobilize the inventiveness and special know-how of ordinary workers, giving their ideas a chance to be put into practice, as was the rule when something useful was discovered by established scientists.

Thus, a broad movement within the communities of scientists tries to put into practice Feyerabend's recommendation that "we must use *all* ideas, *all* methods, and not just a small selection of them" (1967: 173).

There is a healthy tendency today to mix science and nonscience. Thus, in social anthropology one lives in a nonindustrial society in order to try to grasp—by no definite "method"—what is going on.

The line between science and nonscience is not as marked as it once was. One reason is the increasingly frequent practice of not marking "research" as a separate item in the budgets of undertakings that require a mixture of research and many other kinds of activity. Nearly any specialized activity today, in our strange societies, requires some form of research, and usually of a rather practical kind. So why try to disentangle what is so intimately connected?

"Primitive tribes have more detailed classifications of animals and plants than contemporary scientific zoology and botany" (ibid., p. 173). Yes, and it is mainly scientists who are every year bringing more instances of this to our attention—that is, to the attention of people within certain "generalist" milieus. The fields of human ecology, especially social anthropology, are being increasingly cultivated. Students from engineering, business administration, theoretical physics, and other hard-boiled areas crop up in institutes that are concerned with societies very different from our own overdeveloped industrial ones. Unhappily, though, there is a shortage of funds and facilities! Hard science still dominates, as do "hard" techniques, although soft research and soft and "intermediate" techniques are developing steadily. (Cf. E. F. Schumacher's *Small Is Beautiful*.)

Status of Scientists Too High?

"[Scientists] have more . . . authority than they deserve" (Feyerabend 1967: 170; cf. p. 176). Yes, in terms of privileges, but when scientists use their specialties to help solve urgent social problems, for example, problems of

health or resource distribution, why oppose their well-earned status? The urgent social problem here is to increase the status of social workers by giving them the formal education they presently lack.

The status of zoologists, botanists, plant geographers, ethologists, and other “soft” scientists has been rather low within the hard-science establishment. Through the environmental movement, though, these people are not only more respected, they are even listened to by people in power. I do not think we should oppose this status. Their job is difficult enough as it is.

Conclusion: (1) The desirability of a reduction in scientists’ status depends upon what kind of scientific activity we are talking about. (2) Reduction of earnings and privileges is desirable and will probably reduce their status.

There Is No Scientific Rationality

Feyerabend attacks the narrowness of scientific rationality (*ibid.*, *passim*). In some scientific groups and communities, rationality is conceived rather narrowly. Acupuncture, extrasensory perception, herbal lore, and hundreds of other phenomena are rejected out-of-hand.

Broad, open-minded conceptions of rationality have also had their representatives among scientists, however. Today, all the above-mentioned phenomena are discussed and research instigated in order to keep frontiers moving. Social anthropologists such as Carlos Castañeda and Michael Harner not only investigate sorcery, but take part in it as a matter of course. Castañeda’s works are listed in curricula on a par with those of Galileo and later representatives of modern science.

Furthermore, researchers supported by scientific establishments are taking up such themes as Kirlian effects, ozonotherapy, homeopathy, and auriculotherapy, and are doing it within a Hippocratic framework.² Insights found in nontechnical, nonindustrial societies are taken seriously and our own tendency toward provincialism counteracted.

Resistance to Scientific Propaganda

“Build up the resistance to *all* propaganda, including the propaganda called ‘argument’” (*ibid.*, p. 176). Argumentation within scientific activity

may well have a propagandistic function more potent and less easily detected than elsewhere, and so-called scientific textbooks deepen the propagandistic element among people who are less able to test the propositions than the scientists. I would think, however, that modern, highly critical mass-communication research, including propaganda analysis, should continue to be one of the ways in which resistance against any propaganda is fostered—this in spite of its use of argument in the analysis of examples of propaganda.

A considerable problem is that those who are good at propaganda analysis tend to be politically passive, perhaps because resistance to propaganda correlates with resistance to being influenced by any communication. Isn't what Feyerabend has in mind sometimes—for example, when writing articles—resistance to propaganda other than his own?

Research and Lifestyle

"Basic beliefs, such as the theory of evolution . . ." (Feyerabend 1967: 176). It is excellent to try to avoid propaganda in support of theories of the evolution of species. Students might be given an opportunity to acquaint themselves with various beliefs—say, beliefs concerning fossils—in various cultures, perhaps including our own Middle Ages. This would introduce them to the play of the devil, a long-neglected theme, at least at MIT and other prestigious places. I think, however, that one should not shun paleontological materials, for example, the inspection of the bones of a succession of horselike creatures: Eohippus, Mesohippus, Miohippus, Anchiterium, Kalobatippus, and so on—or even better, participation in a refreshing fossil hunt in a beautiful landscape. Again, though, only a small minority are today able to choose how to live and to do research. We need political action in favor of enlarged opportunities for the many.

Some people are able to combine research with anarchist lifestyles and healthy scepticism toward grand theory, whether evolutionist or antievolutionist. A general decrease of available funds for research will make it more difficult except for a tiny elite to combine research with the lifestyles of our subcultures. As before, my conclusion is: not less research, but more *relevant* research—relevant as part of a meaningful life.

Stronger Belief in Magic May Strengthen the Belief in Technical Science

A stress on education in magic might have effects that would be deplorable from the anarchist viewpoint: a strengthened tendency to look upon spectacular natural science as magic. Pedantic methodology is much more important in sorcery and magic than in research. Influence from a public versed in magic might strengthen the scientific establishment rather than the opposition.

Some Science Is Good for Anarchists

It seems that Feyerabend generalizes unduly his experience among admirers of modern big science, especially the cult of science among philosophers of modern physics. Much of the social and historical research of the left-wing opposition has practically all the features that Feyerabend finds lacking in what he calls science: researchers have little respect for pedantic methodology, they believe implicitly in “anything goes,” they are dedicated to radical reform or to “revolution,” their “scientific” pretensions are moderate, they extol cultures other than the industrial, they stress nonintellectual aspects of rationality, and they fight against the elitism and waste of the hierarchical establishment science. If the trend of oppositional research continues for another decade, research worthy of acceptance by Feyerabend may grow to be one of the significant factors in the fundamental change of Western industrial society. After all, the dominant trends in science reflect to a high degree the kind of society in which it functions, and only general changes in society can change the kind of science that dominates. Even if what is dominant today continues to dominate, philosophy (except perhaps for the very academic variety) teaches individuals how not to be dominated by the dominant.

Science and Joy for All

Roald Amundsen in his *Through the Air to 88° North* (1924) wrote consistently as a “researcher.” On every other page there is some note on research: a temperature reading, a perception that no land is to be seen anywhere,

and so on. If we are methodological pedants, we can say that the expedition was 95 percent adventure and 5 percent mild and soft research of sorts. Heyerdahl's expeditions on the *Kon-Tiki*: 94 percent adventure and 6 percent research of the kind that leads to professional reputation. I could mention hundreds of other projects—probably more in these days than in any other age, including the age in which Feyerabend thinks science was not so bad. I refer to research projects that delight the researcher, the public, boys and girls from ten to ninety, and do not cost millions. Entire research communities are alive with such projects, and one can only regret that Feyerabend has lived so many years in the top-prestige and apparatus-dominated environment of quantum physics.

The kind of research I recommend, which I hope will engage millions of amateurs and thousands of professionals in a century not far from our own, will perhaps never be dominant. Why, though, should we look at what is dominant? *Mensch ärgere dich nicht!* Let us never be dominated by the dominant. Spinoza, or our less “fortunate” neighbor, can teach us how to concentrate on what is worthwhile.

General Conclusion

Feyerabend's indictment is primarily an indictment of the financially dominant trends of contemporary science in the overdeveloped industrial or “apparatus” countries. Other trends are supporting radical change. Even if these trends are weak, they are in excellent harmony with certain philosophical and scientific traditions of the past and of many “underdeveloped” cultures of the present. If these trends are destroyed together with the dominant, defective trends, the task of radical reform will be still more difficult.

Appendix

The following is a list of grievances against science found articulated by writers on modern cultural phenomena. I have listed only those grievances that to some extent, and if carefully reformulated, seem to me both justified and important. It is primarily the task of our scientific communities to discuss the grievances and work for reforms where urgently needed.

Current Main Grievances Against Science

1. Science does not speak truth to power. Scientists keep quiet if amply rewarded.
2. Leading scientists take part in creating new, terrible, ecologically devastating ways of waging war. Scientists support any state or regime if sufficiently rewarded. Some serve the state through research on how to torture, taking part in international instruction on how to torture without organized opposition from their colleagues.
3. Scientists do not fight their own elitist and privileged social position. Most scientists support a class society and the status quo in general.
4. Scientists neglect to investigate abuses of their findings and refuse to be responsible. Scientists claim too often, and with insufficient evidence, that they are unable to ascertain how their findings are used and to halt misuse, including uses they consider unethical or even criminal. They organize more readily to secure higher pay than to stop abuse.
5. Scientists support technocracy and irresponsible social engineering; serve the increase of waste rather than the movement to halt irresponsible resource policies; support spectacular science for an elite rather than research useful for developing countries; and support the government's capacity to control through prediction of social events rather than to govern on the basis of explicit value priorities.
6. Modern experimental science tends to be meddling and disrupting, despite its claim to be socially and politically neutral. A widespread aim of science is to control phenomena by predicting them.
7. Scientific research is characterized by disrespect for personal dignity, cruelty to animals and human beings, and usurpation of power over people through questionnaires and interviews.
8. Its adherents teach falsely that science by its very nature supports democracy and freedom.
9. Another false teaching is that science needs no philosophy or metaphysics but has an intellectually indubitable basis in itself. The propagation of the scientific attitude is really a propagation of narrow intellectualism.

PHILOSOPHY OF SCIENCE

10. Science does not serve the people at large, but mainly the well-to-do, the upper strata, and its own expansion.
11. What is called scientific rationality is mostly a soul-narrowing, superficial reliance on the intellect. Scientists lend their weight to the devaluing of insights found outside their scientific communities and look down on cultures that have no science, or very different kinds of science from that of the industrial societies.
12. Science by its very methodology is apt to support “reductionism” and “positivism,” to destroy wonder. Science requires simplification but does not admit that it simplifies. Science supports the unreflective mind and does not insist on a critical examination of its own activity.
13. Science favors a view of nature that invites dominance and rape; tends to lead people away from nature and to favor interference and change as a goal in itself; and supports the belief that nature “really” is colorless, that the physical world picture actually represents reality.

Can Violence Lead to Nonviolence? Gandhi's Point of View

Gandhi called himself an experimenter. His experiment consisted in systematically developing and consistently following the voice of conscience—following it completely and relentlessly, and using no other guideline, religious or otherwise. He spoke in these terms since it was the truth—or truthfulness—value of the voice of conscience that was important to him. The religious element enters with his identification of God with truth and justice. However, he substituted the formula “Truth is God” for the formula “God is truth.” In doing so, he kept his concept of truth but changed his concept of God.

Because he was a *karmayogi*, one who seeks the highest goals through action, it became inevitable for him to take sides in the most violent conflicts of his times. With the standard of truth as his master, it was obvious that he had to fight deprivation, injustice, hypocrisy, and untruth—and equally obvious that this would soon lead him to take part in political battles. The corollary of the identification of God with truth is that living a religious life is equivalent to pursuing truth. The worshiper of God will inevitably be involved in group conflicts.

I could not be leading a religious life unless I identified myself with the whole of mankind, and that I could not do unless I took part in politics. The whole gamut of man's activities today constitutes an indivisible whole. You cannot

THE PHILOSOPHY OF PEACE AND GANDHIAN ETHICS

divide social, economic, political, and purely religious work into watertight compartments.

(Gandhi, *Harijan*, December 24, 1938, cited in Prabhu and Rao 1946: 81)

To see the universal and all-pervading Spirit of Truth face to face one must be able to love the meanest of creatures as oneself. And a man who aspires after that cannot afford to keep out of any field of life. That is why my devotion to Truth has drawn me into the field of politics.

(Gandhi 1956: 504)

One is justified in calling Gandhi a man of peace and goodwill, but one is also justified in calling him the greatest of agitators—he roused millions of Indians to battle. The peasants were indifferent and had resigned themselves to suppression. It had not occurred to them to take part in any conflict until Gandhi called forth demands for justice, and, more fundamentally, demands for humane conditions of existence. He stimulated them to individual indignation at their condition and at the humiliations they were suffering.

The representatives of the Indian empire very clearly foresaw how the standard of unconditional truth, combined with the standard of action, had to create conflict. They were right in supposing that Gandhi's activity would create unrest, disorder, and disobedience. The exchange between the Hunter Committee's counsel and the accused Gandhi, prior to one of his many terms in prison, is famous:

Counsel: However honestly a man may strive in his search for truth, his notions of truth may be different from the notions of others. Who then is to determine the truth?

Accused: The individual himself would determine that.

Counsel: Different individuals would have different views as to truth. Would that not lead to confusion?

Accused: I do not think so.

(Tendulkar 1952: 342)

Of course truth leads to conflict; but it clarifies, it does not confuse. A crucial point, however, is the question of *how* the battle between groups is to be carried out when both sides are relentlessly pursuing the voice of conscience.

It is commonly held that Gandhi regarded as self-evident that the voice of conscience should dictate the nonviolent form of battle as the only

effective and the only justifiable one. This is a fundamental misunderstanding. He fully realized that many will conclude, after an honest and profound appraisal of themselves and the situation, that the use of violence is the only effective and the only right course of action. Insofar as the politicians in India held this opinion, it was their duty, according to Gandhi, to arm. He criticized them for shrinking from openly accepting a program of armament even though they obviously had no faith in the methods of nonviolence. The politicians ought to have provided training in the use of arms if they lacked belief in nonviolence.

Gandhi forced a decision on the Congress Party politicians in 1934 when he proposed the replacement of their catchphrase for action “peacefully and legally” with “truthfully and nonviolently.” The proposal was not accepted and Gandhi left Indian party politics.

The methods of nonviolence are rightly associated with the name of Gandhi. His originality in this field is unique, although some of his methods have been rediscovered independently of him. Martin Luther King, Jr., is one of the outstanding names in this connection. It is often forgotten, however, that the standards of nonviolent conduct and intention are for Gandhi subservient to another standard, the highest standard in his system. He wrote:

If it is possible for the human tongue to give the fullest description of God, I have come to the conclusion that for myself, God is Truth. But two years ago I went a step further and said that Truth is God.

(*Young India*, December 31, 1931, cited in Prabhu and Rao 1946: 29)

Again, in a discussion with a friend he made this point:

“Nevertheless, your emphasis is always on *ahimsā*. You have made propagation of non-violence the mission of your life,” argued the friend, still unwilling to concede the point. “There again you are wrong,” answered Gandhiji. “*Ahimsā* is not the goal. Truth is the goal. But we have no means of realizing truth in human relationships except through the practice of *ahimsā*. . . .”

(Gandhi 1949: 104–05)

Consequently, the doctrine of nonviolence cannot, according to Gandhi, be evolved in isolation from a higher goal, which is beyond the distinction between violence and nonviolence.

The doctrine of nonviolence rises from Gandhi's personal conviction of a fundamental equality in the destiny of all men, and of their equal right to self-expression. His personal identification with all men, however, equates injury to others with injury to oneself. In group conflicts, one gains nothing by injuring others. No fully justifiable goal may be reached by means that include planned or accidental injury to others in such conflicts. Between one's own self-expression and the self-expression of others there is no sharp boundary.

Moreover, the activist program follows from this identification; it does not help to retire from existing battles in order to avoid committing violence oneself. Violence is an evil, whether it is one's own or that of another, and must be fought. Therefore, one must seek the root of the conflict, must go to where violence is beginning or has begun.

Gandhi distinguishes between condemnation of an act and condemnation of the person who has carried out the act. Acts of violence are always wrong and evil, but this does not justify us in immediately condemning the person who acts violently. A person who in a good cause can see only the alternatives of cowardly reticence and violence does right in acting violently. That he should see only these alternatives in spite of intensive analysis of himself and study of the situation discloses a lack of insight or experience, or perhaps a lack of opportunity to train himself in nonviolence because he was brought up in an environment in which it was thought good to be shielded from raw reality. Unless one takes part in agonizing conflicts, the capacity for effective nonviolence cannot, of course, be developed.

Gandhi understood what is now commonly called counterviolence, particularly when the opponent is physically utterly superior. In line with this he expressed understanding of Norway's war against Hitler's Germany. Germany's superiority in that case made violence something akin to a symbolic act—an unconditional *no* to injustice. To small powers that are attacked, Gandhi did not say that they *ought* to offer nonviolent resistance but that they *may*, and further, that nonviolence is in the long run the only thing that can reduce organized violence and suppression.¹

When Gandhi left South Africa and started his work in India, he soon realized that the Indian masses could not immediately be mobilized in a political struggle for freedom.

Can Violence Lead to Nonviolence? Gandhi's Point of View

A starving man thinks first of satisfying his hunger before anything else. He will sell his liberty and all for the sake of getting a morsel of food. Such is the position of millions of the people of India. For them liberty, God and all such words are merely letters put together without the slightest meaning.

(*Young India*, March 18, 1926, cited in Fischer 1962: 223)

Continuous hunger produces apathy. The apathy in India was so all-embracing that it hindered every constructive effort to improve the conditions of life. The situation seemed hopeless: apathy and passivity beget self-contempt, a feeling of being totally useless or superfluous, a feeling of infinite impotence, and hence a lack of personal identity.

It was impossible for Gandhi to make any substantial and immediate change in the food situation. Thus, he had to increase the self-respect of each individual, to increase the belief that "I am something worth caring for," despite the absence of such a change. One of his brilliant schemes to this end was the hand-spinning and hand-weaving program, the Khadi movement. Gandhi said of this:

If we want to give these people a sense of freedom we shall have to provide them with work which they can easily do in their desolate homes. This can only be done by the spinning wheel. And when they have become self-reliant and are able to support themselves we are in a position to talk to them about freedom, about [the] Congress [Party], etc. Those, therefore, who bring them work and means of getting a crust of bread will be their deliverers and will be also the people who will make them hunger for liberty.

(Ibid.)

Gandhi's plan was that every family in India's half a million villages should take part in the Khadi movement by spinning or weaving. Most of the villagers were out of work for most of the year. During this time they were idle, without aim or purpose, and more often than not suffering from some disease. That Indians should henceforth be able to provide for some of their own basic needs became in itself a challenge to the government, and an act of self-assertion on the part of each Indian against his seemingly all-powerful rulers.

The Khadi movement served also to knit the Indian nation closer together. Gandhi prevented the loom from becoming a symbol of poverty by, among other things, passing a resolution that the membership dues of the Congress Party should be two thousand yards of yarn spun by the member

himself. Everyone was on the same footing, and this could only increase the self-respect of the poor in relation to the richer classes.

By means of the Khadi movement and other brilliantly conceived schemes, Gandhi succeeded in bringing into being an elementary minimum of self-respect and feeling of worth and dignity in millions of Indians. This, more than anything else, was his ethical and political achievement. Gandhi then tried to utilize this minimum to get people to join constructive projects on a large scale. As a result of participation in such projects, the emerging self-respect grew into a clear awareness of the right not only to survive but to live a worthy life, and thus of the duty to take part in the political-freedom movement.

According to Gandhi the intimate connection between economy and personal identity necessitated the carrying out of extensive decentralization and the elimination of big cities. In his *Constructive Programme* (1941), Gandhi envisaged that the 700,000 villages in India, instead of being exploited and destroyed by half a dozen cities in India and Great Britain, would be able largely to support themselves and serve voluntarily the cities of India, and even those of the outside world, so far as this was mutually beneficial. This, he said, would require a revolutionary change in the mentality of the masses. The nonviolent way, although easy in many respects, was very difficult in others. It meant touching the life of each Indian, making him feel possessed of a force hidden within him, and making him proud of his identity with every other Indian.

The essential point is this, that Gandhi acknowledged self-respect as an absolutely necessary precondition for nonviolent action in group conflicts. When it becomes obvious that the self-respect is insufficient, the struggle for independence must change its emphasis to measures aimed at increasing self-respect. Indignation and angry words are signs of insufficient self-respect, caused by powerlessness and a lack of belief in one's ability to convince the opponent.²

I give the following as an example of how Gandhi reacted when confronted with instances of abject anger.

In 1921, Gandhi organized the largest nonviolent campaign ever carried out. According to the plan, a constant escalation was to take place, month after month. The decisive phase was planned to begin on February 1, 1922, with collective lawbreaking. In Chauri Chaura, though, the mob

killed twenty-two policemen, cut them up, and burned them, in desperate anger and counterviolence. Gandhi immediately called off the entire campaign, even though it now embraced more than one million men. Only the constructive program was continued, that is, the hand-spinning, the religious tolerance movement, and the help to the untouchables. Many politicians were intensely annoyed, and the multitudes despaired, over Gandhi's reaction.

His motives were clear enough, however. What was important to him was that the conditions for extensive nonviolence involving mass participation were not present. The requirements of self-respect and human dignity were not satisfied. Consequently, a retreat from the political to the more fundamental ethical and humanitarian level was necessary. This entailed intensifying the "constructive" measures. The episode of Chauri Chaura illuminates the importance that Gandhi attached to the preparations for nonviolent action and how clear it was to him that if events disclosed decisive flaws in the preparations, the action had to be called off temporarily or else considerable de-escalation had to take place.

We can find the same pattern in his reaction to violence and counterviolence in Amritsar in 1919. Again, he found that self-respect had given way, and participants had fled or used violence. Gandhi called off the action. He recognized his "Himalayan mistake." The masses had not been sufficiently mature for civil disobedience, a fact that he, as leader, ought to have understood. Collective excitement is a difficult factor to estimate, but it is primarily the sheer number of people involved in mass movements that makes consistent nonviolence difficult. If even one in a thousand is actively destructive, he may be followed by ten others in one violent act that spoils the entire campaign. Of course, encouraging events took place as well. In 1930, on several occasions the multitude stayed where it was when the armed police attacked it, with the result that the police refused to continue the attack (see Bondurant 1958: 96). This was exactly the kind of self-respect and self-restraint on the part of the demonstrators that, according to Gandhi, is necessary for the carrying out of an effective nonviolent liberation struggle.

I will now try to show how Gandhi's ideas on self-respect, and the conviction of personal identity and worth, are relevant today.

The last ten years have seen a lack of belief in nonviolent action within

several liberation movements. Violence both in intention and in action has become fashionable.³ The recognition of violence today springs partly from the conviction that only a small minority are able to remain nonviolent in battle and that brutal opponents are impressed by nothing except violence and are not at all ashamed of assaulting the defenseless.

From close examination of the examples and teachings of famous violence-promoting black leaders, it seems clear to me that Martin Luther King, Jr., and the other eminent advocates of nonviolence in the 1950s did not quite succeed in formulating, much less in solving, the problem of self-respect. Critics of King's strict nonviolence emphasize that a man who is without belief in himself can desist from counterviolence only by cowardice. His reflexes will require him to answer violence with violence. The only question for him is, Do I dare to?

In explaining the lack of self-respect among blacks in the United States, we must consider several factors, social, mental, and religious.

The religious traditions in the Indian societies (including the Muslim) made it easier for Gandhi to appeal to religious and cultural standards than it has been for Martin Luther King, for example, to appeal to Christian standards in addressing the black population of America's secularized industrial society. Furthermore, there has been no unifying, positive, concrete liberation program in the United States, nor any constructive plan such as formed the basis of the Khadi movement in India. This may partly account for the absence of a satisfactory solution to the problem of self-respect in America, and for the rare occurrence of conditions enabling the use of positive, aggressive nonviolence on a large scale.

The difference between the situations in America and India is not, however, that the opponents in India were less brutal. Gandhi's main field was in the area of religious conflicts. When he lost control toward the end of the 1940s, more than a million people were killed in communal riots all over India. Hatred and white-hot anger were features of the situation in which Gandhi and his helpers exercised their power, and it was not "the kind Englishmen" who put his nonviolence to the test.⁴

It is natural to interpret a considerable part of today's direct exhortations to counterviolence, that is, to meet violence with violence, as an attempt to give the apathetic, self-deprecating individual a chance to feel that he *is* something, is someone to whom the opponent must pay atten-

tion. It is probably this that Frantz Fanon has in mind (in his saner moments) when he emphasizes "the liberating effect of violence" upon the oppressed and underprivileged. He says:

At the level of individuals violence is a cleansing force. It frees the native from his inferiority complex and from his despair and inaction; it makes him fearless and restores his self-respect.

(Fanon 1967: 35)

It is worth noting that Fanon mentions the "slave soul" in the same context. There are, in fact, reports from the United States indicating that violence by blacks against the police has had an intensely stimulating effect upon the black population. All have felt themselves a little bigger, a little more courageous. A more straightforward, natural mode of speech is being used in front of the whites. A new phenomenon on the university square at Berkeley (1968) is the sight of blacks cursing whites, who stand in a circle about them listening solemnly and obviously on the defensive. This helps, of course, but only in the short run: it solves no problems.

When the use of counterviolence is argued, the typical situation put forward is that of a colored person assaulted by whites. The black leader Stokeley Carmichael usually speaks of assaults by white mobs and nocturnal terrorists. In terms of the group conflict, however, these are relatively unimportant situations. To Carmichael, and also to others who criticize Martin Luther King, it seems clear that civil rights and a comprehensive participation in the decision process cannot be obtained by fistfighting or individual use of weapons, but it is equally clear to them that these cannot be attained by passivity in the face of assault. Of this, Carmichael and Hamilton say, in their book *Black Power* (1967), that as leaders they increased the frustration of the blacks boiling with anger at the lack of action taken after they had seen Martin Luther King take a rap, and small black girls killed by a bomb in a church, since the leaders had nothing concrete to offer them. Such frustration is understandable considering the feeling of paralysis and the lack of a constructive program. These blacks had nothing to do except go out in the street and be hit once again. The absence of a continuous nonviolent struggle had its effects. To be struck down in a direct battle does not give rise to the frustration Carmichael describes.

From the point of view I have indicated, it is misleading to say that in

the United States nonviolent methods have largely been given up in favor of violent methods. What has happened during the last few years may be interpreted rather as an attempt to create the necessary conditions for a future non-violent constructive campaign on a mass basis. In India, Gandhi succeeded in bringing about the conditions required for nonviolent revolution; in other societies, it seems, these must be brought about partly by violent methods and incidents. It is quite clear, however, even from the statements of extremists such as the Black Panther leader Huey Newton, that counterviolence must not be regarded as a way of solving the major problems of liberation. Violence is conceived of only as a defensive and preliminary measure, a means of counteracting fear, panic, and the feeling of inferiority that is absolutely destructive in any effective organization of campaigns toward liberation.

The latest reports from the United States indicate that the blacks are turning their backs on spontaneous riots and destruction, and are more and more carrying on the struggle with positive action. Cooperation, especially economic cooperation, is popular. Riots and counterviolence may have had their importance, their regrettable function, in an environment in which a kind of primitive self-respect and the use of violence are very close to each other. The use of violence may perhaps have contributed in preparing the ground for the use of more effective means.

The aggressive ideologists within the black liberation movement today find that their situation is similar to that of the Indians insofar as in both cases it is a struggle against colonialism and in both cases it is a matter of revolution. Carmichael and Hamilton conclude their book *Black Power* with the pronouncement that there is a rapidly growing group of blacks who are determined to "T.C.B." (take care of business) regardless of consequences, and who will not be stopped in their vigorous efforts to attain dignity, to grasp their share of power, and to exercise the right to shape their own destiny, here and now, no matter what means may be necessary.

The point to which I am here trying to direct attention is this: the violence that seems to be recommended or tolerated by the leaders of opinion is primarily a means of gaining self-respect and thence the foundation of dignity. "T.C.B." is of course not to be achieved by riots and violence. On the contrary, the blacks were often the hardest hit, economically. Mastery of one's own destiny is only to be achieved by positive measures based on inner strength. Brute force can help only at the very outset. Gandhi envisaged, as

the ultimate measure, forming institutions parallel to those of the oppressors, that is, being self-sufficient on the largest possible scale. To form such institutions, for example, one's own schools, courts, and cooperative societies, positive not negative means are necessary. Blind anger does not further this cause.

Gandhi's campaigns had a character other than what is today commonly called nonviolent. Briefly, we can say that Gandhi's demonstrations were usually demonstrations *for* something rather than against: his agitation was *for* something; his strikes were in the same way constructive; and even his boycotts and civil disobedience were *for*, not against. A campaign *A* was not an attempt to force the situation *B*; rather, the campaign itself consisted in bringing about the situation *B*. It follows that Gandhi's actions were usually directed toward something visible, something concrete and well defined. At the same time, specific aims were included as a small part of the large general aim, the inner and outer liberation.

Many people will say that since Gandhi had as opponents not primitive brutes but the kind and decent Englishmen, his methods cannot be carried over to the racial strife of our time, the wars in the colonies, and student insurrection against police atrocities. The belief that Gandhi dealt primarily with the English stems from the fact that most of the world in the 1920s and 1930s was politically and economically interested in Britain and its empire.⁵ There was little interest in the violent strife among India's cultural constituent societies—among Muslims, Hindus, and Sikhs. Here a white-hot anger raged and, as I have already mentioned, when Gandhi let go the reins toward the end of the 1940s, more than a million people died in the riots among the different communities. Gandhi and his supporters achieved their most shining successes in just those campaigns that were concerned with the elimination of inner strife. Gandhi had good reason to emphasize to Nehru and the more nationalistic political leaders that liberation (*swaraj*) had primarily to mean liberation from the conditions that led to oppression and violence on the inner front. He wished the politicians to concentrate on those aspects rather than on relations with England.

During campaigns, one consequently anticipated and realized something of the future. One taught the opponent how one wanted the society of the future to be. Negative campaigns—those that occurred—were sec-

ondary, and usually in a comprehensible and obvious relationship to the positive aims. They were frequently protests caused by the reactions of the authorities to the positive campaigns, or alternatives to discontinued or blocked positive actions. The fact that the main emphasis was placed on positive, concrete campaigns meant that when the nonviolent freedom fighter met the enemy face-to-face, the former was in the act of *doing* something, or carrying out or expressing something he felt to be indisputably justified. In such a case, the opponent, if he adopts countermeasures, violent or nonviolent, must act so as to counter the positive aim of the nonviolent freedom fighter. For example, the untouchables entered temples and prayed (1924–25 Vekom *satyā-graha*),⁶ or the poor prepared salt from seawater at the coast. The untouchables did not demonstrate outside the priests' dwellings, nor did the poor march in processions carrying posters labeled "Down with the salt tax."

The prevailing interpretation of the commandment to turn the other cheek illustrates the difference between positive and negative nonviolence. It is not particularly difficult to train police to strike down peaceful but negative demonstrators. Passivity under attack makes it difficult for reasonably decent men to beat and abuse people, but if the police are recruited from the ignorant and the authoritarian, or are indoctrinated with the idea that the demonstrations are not advocating any good cause, the element of decency may be eliminated. Even in Norway and Sweden we have seen examples of this. Consequently, the good or just cause must show itself during the confrontation itself, whether this is with the police or with others sent to receive the nonviolent freedom fighters with violence and suppression. One might say that the realization of the positive program so to speak "under the noses of the adversaries" entails the realization of the aims set by the campaigns.

[The] Constructive Programme is the truthful and non-violent way of winning Poorna Swaraj [complete independence].

(Gandhi 1945: iii)

I have said and I repeat, that there is no swaraj for the masses except through Khadi and village-handicraft, for there is no non-violent disobedience without a continuous constructive effort. For a living, continuous mass contact is impossible without a constructive programme, that requires almost daily contact between the (non-violent) workers and the masses.

(*Harijan*, March 23, 1940)

The constructive programme had to be concrete and well defined so that the majority of the members of the society in which the advocates of *satyāgraha* worked could realize that it was to the benefit of all.

The actions during the campaigns themselves were given a positive form, so that the adversary who attacked, using violence, had to do so while the demonstrators were clearly showing what they wanted—for example, while they were entering the temples, or while they were extracting salt for their meals.

During extensive positive campaigns such as the founding of one's own schools, universities, courts of law, and so on, the attackers must destroy something that has an obvious purpose and clearly shows the intentions of the nonviolent fighters. According to Gandhi, this is impossible in a negative campaign since one only shows what one is against. What one is usually against is something well established, something that most people regard as more or less unalterable. To recognize an alternative clearly requires imagination, and we cannot expect an adversary to be in an imaginative mood if the emphasis is on annoying him.

Consequently, the decreasing adherence to so-called nonviolent methods need not be attributed to disappointingly insubstantial results from positive nonviolent actions based on a constructive program. Wherever such actions have been carried through, the result seems to have been remarkably great in comparison with the effort expended. However, the work of Martin Luther King and others, in the spirit of Gandhi, has revealed the importance of learning more about how the prerequisites for the participation of the masses in nonviolent action may be gradually fulfilled.

To sum up, we may say that the reaction against so-called nonviolence is a healthy one insofar as it is a reaction against *passive* resistance and *negative* campaigns. This reaction is likely to lead in the long run to increased acknowledgment and realization of Gandhi's ideas, which clearly point to the importance of the active and positive elements in campaigns. May the centenary celebration contribute to the strengthening of these ideas all over the world!

II

Consequences of an Absolute *No* to Nuclear War

In this essay I do not write as a kind of politician or adviser to politicians, but as a plain member of humanity—except for my special obligations owing to my education and other privileges. If I were to advise a member of a government, I would first consider his or her position, the local power structure, and the narrowness of alternatives for that particular person at the moment. Why is it the duty of a philosopher to speak up on nuclear arms and the future of life, not only human life but, equally important, nonhuman life? A philosopher, by training, has value priorities and maximally wide perspectives in time and space—a total view, however tentative and imperfect. Philosophy is a search for wisdom, the integration of reflection and action, not merely a search for knowledge. A philosopher is not a logician, an epistemologist, a political philosopher. Specialization leads nowhere. In our mammoth industrial societies, a philosopher must fight for the reestablishment of intrinsic, ultimate values in life and against the dominance of the merely instrumental. Increasing militarization is one aspect of the irrational belief that instruments and the pursuit of “power over” can save us in the long run. To threaten with nuclear gadgets is to threaten Mother Earth and is inconsistent with every wide perspective.

No philosophy of great standing gives priority to the accumulation of material possessions, nor does any favor “power over” when compared with “power to,” nor means over ends, nor nonultimate ends over ultimate ends. Philosophers have advocated as part of wisdom a life simple in means and

This article was reprinted with permission from *Nuclear Weapons and the Future of Humanity: The Fundamental Questions*, edited by Avner Cohen and Steven Lee (Totowa, New Jersey: Rowman and Allanheld, 1986), 425–36.

rich in the enjoyment of intrinsic values—values that are values in themselves, not mainly means to a further end. No decision, no policy, no technology is rational if it is not conducive to fundamental, ultimate ends and values. In what follows I take this as axiomatic.

Wise proposals are often characterized as unrealistic because people, while acknowledging their wisdom, are unable to act on them. Such a lack of personal integration is a product of the culture in which we live: our industrial societies do not foster our ability to act from our deepest feelings and broadest knowledge.

I assume, however, that individuals, given the opportunity to develop normally in an environment not degraded in obvious ways, are (sometimes) able to recognize wise decisions and act on them. Further, I assume that we are consciously able to change trends—political, social, and general cultural—at least to some extent. There are reasons to doubt this, but to reject this presupposition is self-defeating and pessimistic.¹ (The “we” I refer to are responsible citizens of nations that today possess nuclear weapons and those who live in industrialized states in general.)

What kind of policy could eliminate the roots (both causes and motives) of nuclear threats?

The Nature of the Current Nuclear Peril

Hostility between the two main nuclear powers has reached a high degree of intensity; nuclear war is a threatening possibility. It may start with a limited exchange of bombs and could stop at that, but it is just as likely to explode into a major nuclear exchange. The short- and long-range consequences of such an explosion would affect not only the belligerent countries, but humankind and living conditions on the planet in general. Such a war could not possibly serve fundamental, ultimate values of life. The situation is of vast planetary concern.²

No political objective, no goal such as “making the world safe for democracy and freedom” or “making the world safe for communism,” could be achieved through a major nuclear war. Moreover, since our planet is not the property of the owners of the bombs, nor of mankind in general, we have *no right* to threaten with bombs.

The nuclear arms of a nation do not deter if an enemy believes that the

nation will under no circumstances use them. It must always be credible that under certain circumstances the nation will use nuclear weapons within limits and go all out in their use in extremis. For the sake of credibility every nation must resort to clear threats, and increasing threats must be met with increasing threats.

The moral permissibility of ultimate full-scale retaliation cannot be upheld. The old way of defending the moral soundness of retaliation was to refer to the principle of just retribution: those responsible for the disaster had to be punished. The chance, though, of killing those really responsible for a nuclear disaster would be slim. Millions of nonbelligerents and innumerable other beings would suffer, whereas people at the top of the power pyramids would likely escape.

The danger posed by nuclear weapons would not be removed even through negotiated disarmament. If nuclear disarmament were realized through international treaties, threats to rearm would probably replace the current threats, and the technological race would then focus on means to rapid nuclear rearmament. Therefore, the threat of nuclear war would not decrease substantially as a consequence of nuclear disarmament among mutually hostile nations. Something more basic than nuclear disarmament must occur, something that has to do with nuclear cultures as *a whole*.

Until recently, the armaments of various nations could be roughly compared because rough quantification was possible. Now, with many different kinds of weapons, a great variety of sophisticated inventions related to speed of delivery, and other factors of major importance, even a rough comparison between the United States and the USSR is difficult. Consequently, the governments are able to make increasingly alarming and *untestable* claims about one being behind the other and thus accelerate a race already feverish in its intensity. To call this self-accelerating race a policy of deterrence is to name it in accord with its intended, but unlikely, result. Basically, it is a policy of military mobilization, making full-scale war possible within minutes.

So-called deterrence, I argue, cannot be a way to avoid catastrophe in the long run. Intense physical and mental mobilization for war has rarely been called off: it is more often a prelude to war. The state of mutual deterrence, if continued into the indefinite future, will almost certainly break down eventually. However, my argument does not require so strong a claim. It is enough to accept the thesis that there is at least a fair chance

that the arms race, if continued for a decade or more, will, accidentally or otherwise, lead to a major nuclear exchange. To avoid this possibility, we must move beyond the policy of nuclear deterrence.

My proposal starts with the observation that if one of a pair of mutually hostile nuclear powers unilaterally disarms, little motive remains for the other to use nuclear bombs. If a military move is made, it will be in the form of occupation or some form of domination from a distance. Thus, demilitarization is the surest means of avoiding nuclear war. It better deserves to be classed as a policy of deterrence than does the continued physical and mental mobilization that goes by that name.

If one side adopts a policy of unilateral disarmament, the worst that could happen is that it would be occupied by the other power. Of course, occupation itself would be seen as a great catastrophe, and here the role of mental mobilization is apparent. The desperate effort to win the nuclear arms race cannot be sustained without painting the consequences of military defeat and occupation by foreigners as worse than anything conceivable, both ethically and in terms of suffering,³ even though nuclear war would in fact be far the greater catastrophe. I consider step-by-step unilateral demilitarization to be the proper road to follow. It must be step-by-step because time is required for the general populace to adapt to the value priorities involved.

In the part of the world in which I live, northern Europe, only one possibility of nuclear war is taken seriously: a war between the Soviet Union and the United States. Among politicians, however, there is also a widespread fear of "Finlandization" if the arms race is not kept up; that is, a fear of dependence that could develop into domination or occupation. Finland is said to live "at the mercy" of the Soviet Union.

Left-wing groups today tend to be as critical of the way the Soviet Union is governed, including its economic system, as are right-wing groups. The significant difference is that the moderate left has a strong tendency to consider Soviet foreign policy as basically defensive, which would make it easier to accept Western unilateral disarmament. I agree with this leftist view but find it unacceptable to take the thesis of defensiveness as a kind of axiom. The hypothesis should be taken seriously that the Soviet Union, at least as much as the United States, is bent on a kind of world policing. Each power is trying to prevent the development of regimes that could strengthen the

other. The policy I recommend assumes, for the sake of argument, that the Soviets intend a kind of world policing. With this assumption and thus the possibility of Soviet occupation, we should note the difficulties that a Soviet attempt at worldwide policing would involve. The way the Soviet Union has tried to protect itself through dominance in Eastern Europe since 1945 is obviously ineffective as a police method on a wide scale. If the United States adopted unilateral disarmament, what would a Soviet government bent on world policing do? No one thinks that a physical occupation by the Soviets would be feasible, nor the establishment of Soviet communism through the very few communists in the United States. (Some authors argue, by the way, that a communist United States would be even more frightening to Russian nationalists than a communist China.) I think that world policing is impossible in the long run by any military means.

Although the Soviets might try, through military exploits, to dominate some new territories, there are strong reasons to suspect that large expansion would be extremely difficult. Soviet domination of Eastern Europe was established through strong communist minorities, and in part through a rather weak attachment on the part of Eastern Europe to the western European social system. Today, Soviet communists are extremely rare the world over, and the regimes that try to develop through Soviet help would prefer to be helped by the United States. Second, the Americans' vast material and mental effort to keep the arms race going would, in the event of disarmament, be used to help those very regimes and, more generally, to foster a desire for social justice that would only be heightened by Soviet military intervention.

A world in which the Soviet Union were armed and the United States were not would have many problems. For example, two minor states at war might ask for Soviet weapons and become politically dependent on the Soviet Union, thus increasing the territories dominated by it. History, however, does not support the belief that empire building solely by such means would last long.

Let us return to the assumption that occupation is possible. Even if the slogan "Better dead than red" is not often heard in Europe, people seemed to hold until the late 1970s that there was nothing worse than being occupied and "conquered" by the Soviet Union. It is, however, of decisive importance that the populace of northern Europe has seriously begun to com-

pare the two evils, nuclear war and occupation. Moreover, the consequences of living with the grave risk of such a war are being broadly discussed. Whereas it once took months or years to amass the materials necessary for a decisive wartime attack, technological invention has drastically narrowed the time between a decision and colossal, indiscriminate destruction. Long-range social and cultural activities cannot thrive in an atmosphere in which there may be nothing the next day to care about. People at the grass roots have started to contemplate these things.

The destructive effect of nuclear war on the conditions for life on the planet and the lack of ethical justification for such a destruction have not yet been widely enough considered.⁴ The destruction cannot be justified on the basis of human political rivalry. This presents a sufficient reason for an absolute *no* to nuclear war and the consequent adoption of a policy of unilateral disarmament. Most people, if given the time and opportunity to assess the destructiveness, stupidity, and ethical depravity of nuclear war, will come to see that occupation and "conquest" of one's country is the lesser evil. I think they will also see that it is ethically unacceptable to participate in preparations for nuclear war in order not to be conquered.

Some would respond to this argument by claiming that, although foreign occupation or domination may be preferable to nuclear war, another, much better way of avoiding nuclear war that leads neither to foreign occupation nor to domination is bilateral nuclear disarmament through treaty. As I have argued above, though, this would not solve the problem: threats to rearm would replace nuclear threats, and the carrying out of the former threats would again create the risk of nuclear war. The only solution is for one side to take the initiative to demilitarize.

The absolute *no* on ethical grounds is contested on the grounds of the relative weight of bad or good consequences. The above argument has shown, however, that the possession of nuclear armaments cannot be justified on utilitarian grounds. In addition, an absolute *no* is supported on deontological grounds. I cannot go into discussion of this point, but only refer to another area where an absolute *no* is fairly well established: the *no* to participation in torture. It implies a refusal to consider the hypothesis that one can save ten from torture through merely preparing for the eventuality of torture. The above argumentation against preparation for nuclear war rests on a double basis, one utilitarian and one deontological.

Cultural Evolution

Saying yes to a credible threat of massive, nuclear retaliation implies a long string of yesses. First, it implies a yes to the nuclear arms race, because the “enemy” naturally seeks to improve his forces to counter one’s own. It also implies an arms race in other than nuclear forms and a more generalized technological race in support of the nuclear developments. A kind of nuclear culture is implied. In democracies as well as in dictatorships, continuous moral support of gigantic military spending is a necessity. In democracies even greater conformity of opinion than in dictatorships is required about the utter necessity of a continued arms race.

In short, a yes to the use of, or the threat to use, nuclear weapons affects cultures as a whole. It affects competitiveness, education, social relations, technological development, the economic system, ethical value priorities, religious teachings, political centralization, organization size, attitudes toward nature, and foreign relations, including relations to the Third and Fourth worlds. In continuing the arms race we must say yes to these undesirable side effects.

The cultural situation is dangerous from another point of view. Not only does the nuclear arms race affect the culture, but the culture in turn promotes the arms race by creating the apparent need for a nuclear defense. Certain cultural traits in affluent industrial countries make us increasingly vulnerable and increase our desperate need to trust deterrence. I shall mention only a few:

1. *Largeness and centralization.* Large organizations can be destroyed more easily than small; large towns, requiring difficult and complex transport of energy, food, and water, are at the mercy of the occupier. Centralization of energy sources, and of resources in general, requires organization on a large scale. Smallness, on the other hand, requires general, basic skills and soft, local technology. Mutual help, group loyalty, and local resilience grow in an appropriate economy of decentralization. Clinging to lifestyles that require largeness and centralization increases the tendency to see only two possibilities: successful, purely military defense, or complete chaos and death. Nuclear deterrence leaves a meager but real chance of survival, so

why not place our trust in nuclear weapons? This way of thinking, taking certain complicated ways of life (never “enjoyed” in any culture until now) as a rock-bottom presumption, fosters an acceptance of nuclear weapons and shows a kind of parasitic relationship between recent cultural development and the arms race.

2. *Cultivation of means rather than ends.* Perpetual economic growth requires strong motivation to invest and strong motivation to buy what is produced. This involves progressive complication and vulnerability of means used to attain desired, intrinsic ends and values. The “good life” requires, to an increasing degree, a gigantic, vulnerable apparatus of organization. Explosive national and economic rivalries must be maintained to continue “progress.”
3. *Cultivation of “power over” rather than “power to.”* By the term *power to* I mean the power by which one can directly realize intrinsic values, and by *power over*, the power of access to means considered useful to secure intrinsic values. Individuals and organizations have material riches or coercive or dominating power over other individuals and organizations, fighting to get as much as possible, but the relation of such power to intrinsic values may remain obscure, sometimes even forgotten. Competition tends to center on “power over” rather than on “power to.” Every great philosophy, whether of the East or the West, has insisted that the really powerful are those who are rich in “power to.”

The wealthy, industrial cultures invite us to compete for “power over,” the sophisticated means to satisfy desires, not real needs. This favors an identification of a loss of freedom with a loss of “power over,” rather than a loss of “power to.” This again favors postures of expansion, domination, violence, and, ultimately, the use of threats of nuclear war to avoid decreased “power over.” It also works toward destruction of the institutions of mutual aid, mutual concern, local sharing, and solidarity.⁵

A successful campaign against threats of nuclear war thus requires deep cultural changes, so deep that the process may be called cultural evolution. If industrial societies are not capable of such evolution, the future of this planet is indeed bleak, for human beings and for other forms of life.

The Way of Nonviolence Under Occupation

It is a strange, but not inexplicable, coincidence that the policies adapted to the demilitarized status of society are substantially the same as those recommended by the Green pole in European politics. Also, but to a lesser degree, the deep ecology movement in Europe and the United States proposes policies connected with these peace efforts. The way of cultural evolution envisaged in this essay is essentially of the kind advocated by the Greens and deep ecology supporters. (Their philosophies and methods are set forth elsewhere in many publications.)⁶ Although only a minority of Europeans have confidence in the replacement of military methods with nonviolent methods, the minority is not insignificant and it is increasing. According to a recent public opinion poll in France, “17% declared they would be ready to *rely* on a system of defense based on nonviolent resistance; only 18% had any confidence in the French strike force as a means of defense.”⁷

I want to concentrate on a subject that is rarely discussed: preparation, especially in small industrial nations, for *occupation* in the context of a larger conflict involving threats of nuclear war. My main reason is the earlier point I made that it should not be taken as axiomatic that demilitarization would not lead to occupation by a militarized power. Here I speak in terms not only of nuclear disarmament, but of complete military disarmament or demilitarization. Beyond an absolute *no* to nuclear weapons, we must seek to avoid the use of any form of large-scale, organized violence.

Two developments must proceed together: demilitarization and education in militant nonviolence. The term *militant* is used because the form of nonviolence contemplated requires many soldierly qualities: self-discipline, loyalty, organizational solidarity, physical (but even more, civil and mental) courage, and training. The word *respectful* might be added to *militant* because of the essentially respectful attitude fostered in relation to any human being. Person and action are distinguished: a person as such has the right to be respected. Yet this distinction can be drawn only if one adopts the way of nonviolence. The distinction cannot be effectively made by those who equate violence with effective resistance. As preparation for nonviolence proceeds, a gradual demilitarization can be undertaken.

According to some, demilitarization virtually invites the USSR or the United States to use its coercive power. They consider occupation of small

nations like Norway a certainty. In deference to this perhaps mistaken but widespread opinion, realistic training in behavior under occupation should be instituted. It involves:

1. Training in communication with one another without access to the mass media and the many technical facilities we now use.
2. Training in communication with the occupation forces—that is, learning the English and Russian languages and acquainting ourselves with the kind of “official” justification the occupier is likely to use and how he conceives his own history and culture. (Lack of such knowledge in 1940 in Norway made it necessary for the home front to warn against discussion with the Germans: the latter were likely to win too many points!)
3. Acquaintance with the rules of survival in prisons and concentration camps (survivors are eager to teach us, if invited to do so); acquaintance with the processes of deportation.
4. Acquaintance with the rules of noncooperation and coexistence with the occupier. Occupied people should welcome personal communication at every level, but refuse absolutely to assist in any kind of military work or work that in other ways is auxiliary to the occupation. They should refuse to accept what is patently untrue or to conform to rules inconsistent with their sense of honor.
5. Training in how to continue teaching children in the absence of schools. If the occupier takes over *all* major organizations, schools will probably have to be shunned. In general, information is needed on how all essential institutions of a community can function and be maintained on the microlevel when they are destroyed on the macrolevel. History shows that even one hundred years of occupation need not obliterate a culture nor, seemingly, destroy its quality of life.
6. Training in local self-reliance. Under occupation it may be necessary to dismember all major organizations, including the economy.

As already mentioned, I strongly object to the tendency to treat the basic defensiveness of Soviet policy as axiomatic. As an axiom it justifies the neglect of an unpopular and frightening theme: what if the Soviet Union proceeded to occupy the smaller disarmed European industrial countries?

There should be a frank and widespread discussion of how the advocates of nonviolence propose to act under occupation, and how people could retain the essentials of their life. Reflection about what constitutes those essentials is, at the very least, required today.

Although I have accepted the assumption that the Soviets would move to occupy countries in the West that demilitarized, and thus that we must pursue training in militant nonviolence, I must repeat my earlier point that such a move would almost certainly be unsuccessful in a major industrial power such as the United States.⁸ Even in Eastern Europe, occupation *by Russians* would have been practically impossible. Large local communist parties believed that the Soviet system was inevitable, and a substantial number of people were willing to police the rest in a crude and brutal way. There is an atmosphere of civil war rather than of occupation in those countries. The Russians are unable and probably also unwilling to occupy them. In places in the West where Soviet occupation is unlikely to be possible, my argument for unilateral disarmament is even stronger. Nevertheless, discussion of the possibility of occupation is valuable, for it points to features of our culture that need to be changed if disarmament is to be possible.

Many people's first reaction to the requirement of increased preparedness for occupation is a grave doubt that the populace as a whole would be willing to participate. If less than the total populace cooperated, various minorities might worsen the situation: a fanatic or heroic minority opposing the occupier with violence, a minority of quislings, or a substantial minority of passivists sabotaging the essential, microorganization work. This is why training in militant nonviolence is needed to prepare the way for disarmament.

Any occupation force that tried to run a country would ultimately rely heavily on the cooperation of the occupied. Their benevolent but consistent noncooperation would place a great burden on the occupier. If Norwegians in 1940 had said to the Germans, "I think your pay is excellent but, alas, I shall refuse to work for you" (that is, to build airfields, submarine bases, and so on), it would have taken longer to occupy Norway, and many more Germans would have had to work there throughout the war.

If the ten top people in each major organization have ten immediate subordinates, and these again have ten each, it would require a million people to take over the six upper levels of the structure. In Eastern Europe a

sufficient number of collaborators means that the occupier does not have to control all the way down to the levels of the neighborhoods and local community.⁹ I am convinced that two million more or less ideologically uninterested occupiers could not subdue a country of ten million decentrally organized resisters.

There is another factor to consider: It is an understandable policy of the Soviet Union at all costs to avoid contact between its own people and those of any country with a higher standard of living. This makes it imperative to limit the number of Soviet citizens in foreign industrial countries to highly trained, constantly supervised officials, and to soldiers safely contained in barracks. To mingle freely and take over jobs in the economic life of an occupied country is out of the question.

In the past, people being occupied have usually prepared some kind of violent resistance in advance. The occupier expects this response, and it elicits a violent reaction. Moreover, the occupied people usually try to restore their large central institutions, and this inevitably provokes a massive response by the occupation power. (The fate of Solidarity could be instructive.) Institutions must be maintained on the microlevel until the occupier is convinced that nothing is to be gained from the costly occupation. Why is it so costly? Resistance of the conventional type during occupation is not focused on economies: the occupiers print vast sums of paper money with which they pay the populace to work for them. Nonviolent resistance is less heroic but costs the occupier much in the long run. The occupied do not accept the new money, and the occupier must pay the bureaucracy needed to occupy.

Of course, there are many objections to the policy of nonviolence. Advocates of the use of military power ask, What would a nonviolent resister do in a particular contemporary warlike situation, for example, one hundred meters in front of advancing tanks? On the other hand, defenders of militant, benevolent nonviolence tend to argue more abstractly and from history—for example, How could Hitler have been stopped through non-military means? The defender of military power asks rhetorically how armies can be stopped nonviolently: “by lying down in front of them?” The defender of nonviolence invites us to consider a train of events since, let us say, 1918, or even earlier. A minority sought to help the German democratic politicians by providing food for the hungry (not shutting off the flow, as happened in the winter of 1919). Also, a minority attacked the financial

abandonment of Germany by the West during the great economic crisis of the early 1930s. The defender of militant, benevolent nonviolence resorts to history, saying, If a minority favoring a certain nonviolent policy had been stronger, then the question of a military solution would not have arisen. Both ways of arguing have weak and strong points.

A similar polarity of argumentation makes itself felt concerning the consequences of actions: the first group stresses immediate consequences; the second, long-range consequences. This essay stresses the long-range consequences of a continuing arms race and the continuing adaptation of the whole culture to participation in nuclear war. The two groups have a slogan in common: freedom. However, the term has many shades of meaning, and here they differ.

It is common in industrial democracies to identify a gain in level of freedom with a gain in individual influence over social arrangements, rather than a gain in self-realization, that is, an increase in the power of the whole personality to realize basic, intrinsic values.¹⁰ Again, there is confusion of "power to" with "power over." The tension between Nehru and the Indian nationalists on the one side, and Gandhi on the other, is an example of this and of great significance for world history. For the first group, the key slogan *swaraj* (self-rule) meant political independence. For Gandhi, political independence was never treated as an ultimate, intrinsic value. For him, *swaraj* included the eradication of mutual threats between religious groups. *Swaraj* required a level of maturity that could make political independence work to the best for the nation as a whole. In the West we must keep in mind that the self alluded to in Gandhian *swaraj* is not the abstract ego, but the eminently, socially engaged, mature self.

Participation in plans for nuclear retaliation to maintain political freedom neglects the concept of freedom as understood by Gandhi as well as by central Western philosophers. To invoke love of freedom as the motive for the nuclear arms race is to debase the very ideals of freedom.

The discussion of freedom and resistance under occupation invokes the question of the essentials of a way of life. In spite of differences in ways of life today among those who feel they lead a good or satisfactory life, *kinds* of requirements are held in common.¹¹ Easiest to define are the biological and physiological requirements, such as food. Psychological requirements are more difficult to define, and their presence much more difficult to test, but

they would include felt security, being loved and loving, being respected, self-fulfillment, engagement, meaningfulness, and so on.

In discussions of the hardships under dictatorships, “felt security” is foremost among the psychological factors. Declared opponents and their families may never be sure that some terrorists hired by those in power will not suddenly arrive and drag them from their homes. (An example of felt security is the British definition of nondictatorship: you know it is only the milkman making a noise at the door at 6 A.M.) Felt security today, however, is perhaps no greater than under occupation.

The evils of occupation, as experienced during the Nazi occupation of 1940–1945 in Scandinavia, were those of restricted public communication: everything printed was censored. A large amount of opinion and information could only be communicated to large groups “illegally.” People caught in the production and distribution of such material were imprisoned and sometimes tortured. Schooling, a kind of communication to large groups, was interfered with: there was pressure to change the content of the communication. Again, resisters were prosecuted. Clearly, though, those evils, which resulted in the laborious organization and development of networks of small-group communication, could not compare with what is likely to happen after a nuclear war. The population’s mental health and degree of satisfaction with life were not very much lower, I have reason to think, during the occupation of Norway than they are now. The fundamental evils of prolonged occupation by a state like the Soviet Union are likely to be social, cultural, and mental, rather than physical.

Again, though, the effects of nuclear war, and the kind of society likely to develop after such a war, represent losses of an entirely different order and evils of a completely different ethical kind. Whereas nonviolent resistance under occupation tends to heighten the morale of the populace, strengthen its will, draw people of different classes together, and deepen their consciousness of their own culture, the vision of territories after nuclear war is one of extreme demoralization.

Conclusion

In a poor Indian village it is more rational for each farmer, as an individual, to have five sons rather than one, but for the village as a whole, this is

deadly. For each nation, taken separately, security, as conventionally defined, rests on competition and the arms race, but for humanity and the planet this is absurd, since their security in the case of an arms race inevitably decreases.

Unilateral demilitarization takes the opposite course and starts with the planetary view. Security, as conventionally defined, is zero or very low, to the extent that occupation is a possibility. When defined in terms of power to defend the essentials of a way of life, however, security is not zero or low. How high it is depends in part upon the material requirements of the essentials, the degree of unattractiveness of occupation, and the tendency among other nations to take the planetary rather than the isolationist view.

The likely effect of a full nuclear war is such that one has to say absolutely *no*. This implies saying no also to participation in the current preparations for nuclear war, that is, to the policy of nuclear deterrence. It implies a no to conventional armaments, which, within a short time, can be developed into nuclear armaments. It implies a policy of gradual unilateral disarmament.

Countries that unilaterally demilitarize have to take seriously the possibility of occupation. Defense means, in this case, defense of the basics of a way of life. The only promising way to assure this is the militant nonviolent way. Implied in that way are deep cultural changes, which cannot occur as long as there is preparation for participation in nuclear war. Therefore, the first step is the rejection of participation, whatever the circumstances.

The work for this long-range goal does not preclude wholehearted participation in current peace movements with more limited goals.

Nonmilitary Defense

The traditional means of defending life and freedom include a major emphasis on the military. Because of technical developments, the use of these traditional means could result, in ten or fifty years, in there being few human beings left to enjoy freedom or to struggle against tyranny. Nonmilitary methods of struggle also exist, however. It is the aim of this article to explore to what extent these nonmilitary methods might be developed to serve more adequately the need for means of defending life and freedom, and along what general lines such a change might operate. I do not claim to offer a panacea, a detailed blueprint, a final answer to every aspect of the problem, and certainly I do not offer an easy way without risks. There is no realistic response to the current crisis that does not involve risks. Here I am merely seeking to establish a reasonable case for why we should seriously consider an alternative method of defense that has, relatively speaking, been ignored. Having in mind the defense of the way of life of people with whom I identify—primarily Norwegians, but also many others in many countries—I shall attempt to broaden the traditional concept of defense and defense institutions. It is my belief that thinking in terms of the broader concept will strengthen the possibilities of peace and freedom.

The Inadequacy of Military Defense

The need for defense is greater today than ever before. The decline in the importance of military defense does not reduce the importance of defense in general.

This article was reprinted with permission from *Preventing World War III, Some Proposals*, edited by Quincy Wright, William M. Evan, and Morton Deutsch (New York: Simon and Schuster, 1962), 123–35.

To defend Norway today means to defend our independence, our freedom to shape our lives within the framework of Norwegian social traditions and culture, and to change them as we wish. It is to defend a way of life against all external forces that would alter it without our consent. From experience we know that events in another country can endanger our freedom. Throughout the world there exist dictatorships or power concentrations under various labels that for ideological, economic, military, and other reasons may threaten the freedom of other countries. The Soviet Union is one of them, and I share the view of those who are convinced that a continued advance in power and influence of the Eastern bloc sooner or later may reach the point at which Norway could be taken within that bloc's sphere of influence and possibly be occupied. This would clearly threaten our ability to form our own institutions, and might even involve the deportation of our people to the expanses of northern Asia.

In the event of nonnuclear war, Norway might hold out for hours or even weeks, but in any war between the major blocs we must expect occupation under a more or less benevolent or malevolent military dictatorship. If the war should end with the (so-called) victory of those states introducing a way of life we despise and a totalitarian state machinery, conditions resembling those of the occupation during World War II would again exist. Even in the event of the establishment of a world state, it will be necessary for the peoples of the world to develop means by which to check the possible abuses of power and dictatorial tendencies that could arise from such an extreme concentration of power.

What means of defense happen to be the most effective is relative to what is to be defended. In defending a way of life, we must avoid those means that would undermine or destroy the way of life to be defended and the very people who cherish it.

For hundreds of years the world was such that the defense of Norway could be identified with the defense of Norway's geographic borders. Defense of a territory against physical invasion was often defense of a way of life, a cultural pattern, or an ideology. In this context, military forces strong enough to keep the invader out were conceivable and possibly were effective. Today, however, we recognize that the relative independence we enjoy is the result of many forces and conditions outside Norway. It is these

forces and conditions that we must seek to influence in order to preserve our independence. Military preparations are inadequate to the task.

Against a powerfully armed totalitarian state, military defense of Norway's geographical boundaries by its 3.5 million people¹ alone might be heroic, but it would inevitably be futile and quixotic. Allied with NATO, we increase our military resources, but those resources are not in the long run more effective. As well as increasing the likelihood of occupation during a major war, alliance with nuclear powers makes more acute the danger of annihilation by nuclear weapons. Even though not a single enemy soldier crossed our borders, our existence could be terminated. It is also possible that strong alliances would force Norway to fight nuclear wars for aims that most of its inhabitants do not consider basic or of supreme value.

Hence, the very notion of defense needs clarification. Simply *to call* something a defense measure does not make it capable of defending anything whatsoever. Let us therefore read "military defense" as meaning "military preparation for the eventuality of war." Military preparation is the most thoroughly institutionalized means of defense, but there is no good reason for narrowing down the concept of defense by identifying military defense with defense in general.

Nonmilitary Defense

As wars have become increasingly more destructive, there has grown up a conviction that the use of modern weapons is justified only, if at all, in the service of fundamental values. At present, however, foreign policies are generally shaped, not to protect and extend fundamental values, but to uphold or change existing power relations in favor of this or that nation. Military means may still to some degree be effective for such customary aims. A foreign policy shaped mainly to protect and extend fundamental values could scarcely make use of modern weapons and thus risk a nuclear war, because a war would violate some of those values that are to be defended.

Immediate dissolution of military defense organizations is not likely to realize the aims of those who believe in substituting more or less completely nonmilitary methods for military defense. If at present the military organizations were to be greatly reduced unilaterally or even universally, it is probable that many people would feel more insecure, threat-

ened, and helpless than ever; the passive state of despair and fatalism would actually be reinforced. If one takes away the only means of defense a person *believes* to be truly effective, he certainly has every reason to feel frustrated. Thus, a reduced reliance on the military must be preceded by *the development of increased confidence in and the gradual adoption of alternative means of defense*.

Let it be quite clear that I do not advocate what is usually called pacifism as an alternative to present policies. As an organized movement centering on individual conscientious objection to participation in war, pacifism must from the political scientist's standpoint be regarded mainly as nonpolitical. It is also clear that although pacifists are not always without political influence, they have no common platform. What I am interested in exploring is a primarily nonmilitary defense policy determined by the political and military realities of our day. In light of the current political situation, such a policy cannot call for immediate disarmament.

Commitment to Freedom

Since a nonmilitary defense policy depends on the active participation of the populace in times of emergency, it is vital that the citizens understand what it is that they are trying to defend. The first stage in developing a nonmilitary defense policy is therefore the clarification of the principles that we value and the qualities of the way of life we wish to pursue, so as to increase our commitment to these principles.

Various steps might be taken that would further this understanding and commitment. The most apparent need is for a national self-examination by all parts of the population concerning what it is in our way of life that we cherish and wish to extend and preserve. Discussion groups, panels, debates, articles, books, essays, and radio and television, on both local and national levels, must be enlisted to facilitate this self-examination. Every scholar interested in the question should be provided with the opportunity of obtaining funds for study and publication. Schools, universities, churches, and other educational institutions could serve as local centers for this national program.

This program might be called ideological, but the term must not be confused with ideologies as detailed systems seeking to force compliance

and converts. What is needed is work on the ideas, ideals, and moral convictions associated with freedom, not with force. It is, of course, possible and desirable that an effective program of this kind might influence other countries and contribute to the liberalization of potentially aggressive dictatorial regimes. This would be one demonstration of the direct relation of this program to the problem of defense. On the home front, it would strengthen the motivation for defense and assist in the mobilization of defense energy in times of crisis.

International Service

The second general policy that would in the long run contribute to a fulfillment of our society's ideals and the meeting of human needs as well as to defense is *international service*—service to friendly countries, “neutrals,” and potential enemies alike.

Thanks to Henrik Wergeland, Fridtjof Nansen, and others, there is in Norway a tradition stressing global solidarity and responsibility. If the opposition to the programs advocated by Nansen had not found such strong backing in various powerful countries, there might have developed forms of cooperation on the international level that would have reduced the likelihood of wars. Since 1945, Norway has organized help to countries in which physical disasters have occurred (floods in Italy and Holland, an earthquake in Morocco, etc.). Fisheries in India have been supported in various ways with combined government aid and voluntary contribution, and a variety of other activities have been carried out, all of which might be said to exemplify international service. Other countries have made similar efforts, sometimes more comprehensive and better organized.

It is now time to show the close connection between such measures and defense, and to try to make such international service more effective on a larger scale. Such enterprises need to be integrated into the country's normal economic system, for example, by lowering import duties on products from areas that we assist and encouraging an expansion of trade with them. In addition, it is important that there be some kind of reciprocal aid, such as cultural programs, with the countries receiving assistance. It is cooperation and *mutual* aid that will reduce tension in the long run, and not simply humanitarian help.

International service should be undertaken for its own sake, to relieve suffering and meet human needs.² It is also important as a means of expressing and implementing our nation's way of life and principles, particularly the concern for human dignity and justice and freedom upon which we like to think our society is based. To undertake international service purely from the "ulterior" motive that it will assist our own defense effort will reduce or destroy many of its intrinsic values and its contributions to that effort. However, it is important to recognize the relation between such efforts and the defense problem.

First, in relieving suffering and poverty, international service will contribute to the removal of important causes of conflicts and wars. The relationship of poverty, gross inequality, and suffering to violent conflicts, hatred, and war is too widely recognized to require detailed elaboration.

Second, such programs increase "man-to-man" contacts and contribute to the development of personal loyalties between individuals of various countries. These "crisscross" loyalties can contribute to international solidarity and make it more difficult to obtain popular support for international conflicts with countries with which such contacts have been rich.

Third, international service can contribute to the creation of a more sympathetic attitude toward our country and way of life, which would reduce the chances of aggressive action against us. The potential attacker would have clear evidence of our nonaggressive intentions; and the fear of alienating "world opinion" would make him hesitate before invading. Moreover, in the event of a crisis our plight would receive more attention, publicity, sympathy, and concrete aid than might otherwise have been possible.

Fourth, carrying out an international service program will make our own country better prepared to meet crises. It will help to create a positive sense of purpose and mission comparable to that which often accompanies military efforts, but without certain of the disadvantages of such measures; and in giving our citizens experience in working cooperatively in a common altruistic cause, it will enhance their ability to practice this cooperation in other tasks in times of crisis.

Fifth, knowledge of international service conveyed to the troops and population of a potential enemy might reduce their motivation to act aggressively against us, cause them to carry out repressive orders inefficiently,

and increase the chances of their deserting and mutinying in support of freedom.

Areas of Service

A broad program of international service would include a multitude of tasks. Emergency help in cases of natural catastrophes and famines³ and aid to refugees⁴ would be vital. Technical help adapted to the needs and cultures of the countries desiring it is an obvious means of international service. Another is various types of educational aid, particularly assistance to students who wish to study in other parts of the world.

A service of a somewhat different type is to provide independent observers and investigators to assist in the study and resolution of specific international conflicts and perhaps of certain national political crises such as civil wars. This service would include operational research aimed at contributing to the solution of such conflicts and more general and fundamental research on conflict, war, and nonmilitary means of conducting and resolving conflicts—in short, on much of the nonmilitary defense program advocated here. The results of such research should be widely distributed. Other countries wishing to adopt a similar type of defense policy could be provided with special defense liaison officers, lecturers, and consultants to assist in the adoption of such a program.

Such a program of international service would, of course, require considerable resources, which I am convinced should be provided mainly through the government budget. There would also be a large demand for manpower, including both untrained workers and specialists. In addition to a highly trained long-term technical staff, persons serving for one or two years would play an important role. Volunteers alone could not fill the demand. Manpower should therefore be supplied by conscription from the country's youth of both sexes. This form of service ought to be a full or partial alternative to the usual military conscription or alternative service for conscientious objectors. Essential training would include language skills as well as knowledge and techniques required for particular jobs.

It would be by far preferable if such a service corps could be organized on an international basis and made available to the United Nations or some other international body. The experience of several countries' corps mem-

bers working together—the Americans and Russians cooperating in building a steel plant in India—would contribute to closer understanding and develop the ability to cooperate in service projects. This might make resolution of other issues between such countries less difficult.

A considerable part of such a service program could be carried out through existing organizations that already operate along the same general lines, such as the Red Cross, Save the Children, and War on Want. Other services could be conducted through national branches of international organizations; others, through contributions of men and resources to such international organizations as UNESCO, UNICEF, WHO, and FAO.

Improving Our Own Society

Another aim of a nonmilitary defense program would be to make our own society worthier of defense and more capable of being defended by nonmilitary means. It must be frankly admitted that there are many aspects of our own society and others that many people would not wish to defend, and would certainly not make great sacrifices to defend. The victims of racial segregation and discrimination, for example, and those subjected to economic and political oppression, will not be eager to defend their societies against foreign aggressors who may claim to be “liberators.” Neither will the more idealistic members of such societies, even though not victims of such policies, be eager to sacrifice heavily in the defense of such conditions.

At the time of Hitler’s annexation of Austria, for example, Schuschnigg had already established a one-party system, had built concentration camps on the German model, had abolished individual liberties, and had carried the principle of authoritarianism to its ultimate implication. There remained in Austria little basis for ideological resistance to Hitler. Similar although perhaps less severe conditions existed in certain other European countries, such as Poland and Yugoslavia; apart from the warnings of psychological warfare, there was in many cases no basis for universal and determined resistance to Hitler. Societal housecleaning is a prerequisite for effective nonmilitary defense.

Another necessary improvement is the decentralization of decision-making power. Citizens must be more accustomed to making decisions individually and in small groups and less dependent upon the government or

leaders of organizations. Admittedly, technical developments seem to have made inevitable a certain amount of centralization. However, if the opportunity for local initiative and responsibility is destroyed rather than actively cultivated and nurtured, then the ability of citizens to resist encroachments on their freedom will be disastrously affected. What is needed is a general strengthening of those institutions in our society that can train the individual to make decisions in times of crisis in the absence of the top governmental hierarchy and of all other major organizations. This would prevent demoralization if the state apparatus were seized by opponents of liberty and yes-men placed in key positions in all major organizations.

Nonmilitary Resistance

All of the above components of a nonmilitary defense policy will contribute to the nation's ability to cope with crises; and at the same time they will enrich and improve our own society. They will also reduce the chances of invasion and occupation. It is nevertheless necessary that we have an adequate program for dealing with the latter eventuality, for with modern weapons it will always be possible to invade and occupy territories for shorter or longer intervals. Unhappily, the customary identification of military defeat with total defeat prevents discussion at government levels of problems of occupation and suppression, such discussion being associated with defeatism or lack of "defense-mindedness." The opposite is actually nearer the truth; those who identify military defeat with total defeat neglect a sector of defense of vital importance.

Perhaps the most positive way in which a small country like Norway could contribute to the prevention of a nuclear war would be to say *No, thank you* to an offer from a friendly superstate to stop an invasion of her territory by using nuclear weapons. Such a policy is, however, irresponsible so long as the populace is no better trained to meet the problems of occupation than it was in 1940. As I have indicated previously, reliance on military methods of defense cannot be diminished until other means of defense are generally recognized as equally effective. It is therefore my proposal that, for the present, side by side with conventional military preparations there be instituted a program of preparation for nonmilitary resistance in case of invasion. As popular confidence in such measures gradually grew, it would

be possible and desirable to reduce the military preparations and to rely in greater degree on nonmilitary training.

In the event of invasion by an army possessing nuclear weapons, relatively little could be done by military means to prevent the invader's disbanding major organizations and eliminating known leaders of opposition. Our citizens must understand that this military failure does not mean defeat; it does mean that the struggle is entering a new phase of more direct confrontation of human forces. The struggle ought not to be waged on a front where the opponent already has overwhelming superiority. Rather, it must be waged by nonmilitary weapons and by techniques that can continue to function regardless of the invader's control of communications, ammunition, and supplies, and despite his power of mass deportations. Also, there is likely to be an inverse relationship between the degrees of military and nonmilitary preparedness for defense, for precisely those humanitarian values that give rise to spontaneous loyalty and affection for a way of life are likely to become undermined to the extent that military preparedness is maximized.

Techniques of Resistance

It must be kept in mind that our ultimate goal is to preserve our way of life. Hence, even under enemy occupation certain fundamental principles must be upheld, regardless of what the opponent does and regardless of the cost. *No human being is to be sacrificed by others to achieve an end; each person must be something of a goal in himself. No goal can justify destruction of respect for truth,⁵ and under no circumstances may any human being be mistreated or tortured.*

It is important to distinguish this kind of a program from psychological warfare, which may resort to all types of threats and deception in verbal propaganda. It must also be distinguished from a program of general noncooperation, a program focused on the invaders. The weakness of a policy of general nonviolent resistance is that it should not be upheld at all costs; if repression gradually stiffens, it is impossible to continue defending, for example, the major organizations of a democratic government. Automatic refusal to cooperate with the invaders in food distribution may result in a famine. Self-inflicted hardships for nonessential goals cannot easily be asked or expected of a populace except in critical periods of very short duration.

Techniques of resistance that would serve to defend the above principles could include many types of noncooperation: strikes, boycotts, civil disobedience, refusal to operate and participate in the existing governmental agencies and other major organizations once they had been taken over by the enemy, and refusal to provide him with labor, transportation, information, and so on.⁶ Wherever the invader sought to extend his power by forcing the inhabitants to violate the basic principles, he should be met with those forms of nonviolent resistance best adapted to each case. Let there be no pretense that the enemy would not retaliate and inflict repression. This, however, is no argument against nonmilitary resistance, for it is at least as true of military means. The question is *how* to do the job, not whether it should be carried out.

At the same time, a large variety of efforts could be undertaken to encourage the occupying soldiers not to carry out measures that must be resisted by the inhabitants. These efforts would, of course, include no acts of terrorism against the soldiers themselves. Rather, by means of posters, underground newspapers, secret radio broadcasts, acts of resistance and defiance, and personal contact where possible, the soldiers could be convinced of the pervasive and tenacious nature of the resistance offered. The history of recent occupations—for example, that of Norway—shows that it is possible for occupying soldiers and even high officials to be actively sympathetic with the occupied populace, to be lax or even negligent in carrying out orders, and to pass on important information to the underground. While maintaining the noncooperation and defiance, the resistance should be aimed at maximizing the amount and degree of this support from the occupying forces.

It is vital in such resistance movements for people to be willing and able to continue their customary ways of life in small units when the public life of a democracy is absent. During the occupation of Norway, for example, the teachers successfully prevented the schools' being used to spread false information in the interest of the invaders. Further, by mass nonviolent noncooperation they openly refused to participate in the teachers' organization that Quisling was creating as part of the foundation of his corporate state. When the schools were closed, they taught in homes. The price was months in concentration camps for hundreds, but both the organization and the corporate state were stillborn and the schools remained free of control.

During the German occupation of Poland, the pressure on school-teachers was in part so heavy that direct resistance at the schools and within the school organizations was impossible, but teaching was conducted “privately” in tiny groups, a form of *microresistance*.⁷ In Norway, repression and brutality did not reach such a high pitch that all large organizations, “legal” or “illegal,” were destroyed, but given another five years of occupation, under steadily worsening conditions, the resistance might have disintegrated into microresistance. This would also happen in the case of large-scale deportations. If the citizenry were thoroughly prepared, however, even microresistance could be a weapon far more powerful than any military means used against it.

Research

Military defense methods have been carefully studied for centuries. Non-military methods cannot be improvised. In fact, we do need study and clarification of nonmilitary methods, and training and preparation in the use of such methods in specific situations. Moreover, we need it now.

We have already obtained sufficient practical experience to indicate that, in the light of the obvious limitations of possible alternatives, such nonviolent resistance constitutes the best available means for combating an occupation. There has, on the other hand, been little academic study of these phenomena; our knowledge about them, as compared to techniques of war, for example, is extremely limited. Therefore, a first requirement is the initiation of a large-scale program of fundamental research on nonviolent resistance. In addition to this basic research, specific attention must be paid to the application of such methods against totalitarian opponents. This must include study of totalitarian systems and of the experiences of previously occupied countries under such regimes. Much of the research could be conducted through existing institutes for social research, defense academies, and universities, although it might also be desirable to establish a special institute or academy for coordination of such projects. This program of study cannot wait until a nonmilitary defense program is adopted; it could begin immediately. It will also be necessary to train and develop a core of specialists in such methods: theoreticians and strategists coming from the military, from a variety of academic disciplines such as sociology,

political science, and psychology, and from among those devoted to nonviolent philosophies.

Conclusion

These, then, are certain aspects of a nonmilitary defense program whose primary purpose is to preserve and extend liberty and to prevent invasion and expansion of suppressive systems. It is a program also capable of dealing with invasion and suppression.

We must recognize, of course, that such a program of nonmilitary resistance depends on popular acceptance of the probability that the invader will inflict severe repression, torture, and executions, and that the nation will neither be in a position to retaliate in kind nor be willing to do so. Only such a program, however, could keep alive and active both those principles that furnish the ultimate basis of freedom and the willingness to fight for freedom.

Implementation of a nonmilitary defense policy could be cumbersome, it is true. Such a defense policy involves a reorganization of the existing defense department and a broadening of the tasks of the department of foreign affairs. It is possible that the two might effectively be combined under one or the other auspices, or a new arrangement created. The cost of a nonmilitary program would be considerable, and at the start it might have to be an addition to the current military budget.

This is admittedly not a program that will be adopted in a day, but whereas initial adoption of the policy may be difficult, once the program is worked out in fuller detail and put into practice its adoption by many countries will be facilitated and accelerated. As more and more countries adopt such a program, the dangers of war will be further reduced as greater pressure is exerted for the abandonment of military aggression. In short, it may well be that the only direct means to achieve the fundamental social change required for the permanent prevention of war is the widespread and immediate implementation of the policies of nonmilitary defense.

An Application of Empirical Argumentation Analysis to Spinoza's *Ethics*

The Propositions of the *Ethics* Conceived of as Arguments in a Debate

Nobody today maintains that Spinoza is not an original philosopher. Nevertheless, Harry Austryn Wolfson (1958)—that extremely learned historian of ideas—set himself the task of finding out which sources Spinoza used, or may have used, in formulating each detail of his main work, the *Ethics*. With extraordinary success, Wolfson traced *influences* on Spinoza's formulations. One task of argumentation analysis is to transfer the historian's results, which are formulated in terms of influences, into a rich set of patterns of argumentation. This is a task of hypothetical reconstruction. It clarifies the cognitive content of a historical text by pointing out contrasts and by explicating agreements and disagreements. It rejects the existence of sovereign pronouncements made in a kind of communicational vacuum.

Although *influence* is primarily a causal term, it also has wider connotations, including the transfer of opinion through verbal deliberation and argumentation. Wolfson's conclusion is that Spinoza, perhaps more than any other great philosopher, picked up opinions from others, but that he never did so slavishly. He subtly changed *everything* in his own direction. Thus, when studied deeply, every single proposition in the *Ethics* is seen to have a

SPINOZA

distinctive Spinozist color or flavor. It is, in my opinion, as if to Descartes, to Hobbes, and to a host of other thinkers, Spinoza has said “Yes, but. . . .”

Furthermore, I take Spinoza to have had an intensive intuition concerning existence in general, a genuine *Weltanschauung* (stressing *Schauen*), which simplifies many things and which unifies his own views.

With these two assumptions in mind—the Wolfsonian assumption of “Yes, but. . . .” and my own assumption of a unifying and simplifying intuition—I shall now comment on the vast set of theses of equivalence in the *Ethics*.

Spinoza’s Theses of Equivalence

Spinoza connects about ninety basic terms in his *Ethics* by means of a great number of theses containing what I shall call *expressions of equivalence*:

A is one and the same thing as *B*
A, which is the same as *B*
A is nothing other than *B*
A cannot be anything other than *B*
A signifies the same as *B*
A and *B* signify the same
By *A* and *B* I understand the same
A is called *B*
A, that is, *B*
We say *A* when *B*

Some expressions I classify as expressions of equivalence even though they do not always suggest a close relation between *A* and *B*:

<i>A</i> or <i>B</i>	as in	<i>Deus sive Natura</i>
<i>A</i> or <i>B</i>	as in	<i>Causa seu ratio</i>

If all sentences containing straightforward equivalence expressions are marked by “*A* eq *B*,” it is clear that they make up a large class of important formulations in the *Ethics*. A list of about 250 equivalences (Naess 1974a) is still not a complete list. Each of the following eight central terms occurs either as *A* or as *B* in more than fifteen sentences of equivalence: *causa*, *Deus*, *essentia*, *idea*, *natura* (or *Natura*), *potentia*, *ratio*, *virtus*.

If it is tentatively accepted that such relations of equivalence are transitive, then a vast network of equivalences is created.

Sentences expressing equivalence occur in great numbers in Spinoza's proofs and thus are clearly indispensable in his argumentations. Of sixty-seven equivalences extracted from propositions 1 to 73 in part IV of the *Ethics*, fifty-seven are made use of in proofs.

In a list of equivalences in this set of ninety basic terms:

<i>aeternitas</i>	occurs in	5	equivalences
<i>affectus</i>	"	19	"
<i>amor</i>	"	10	"
<i>anima</i>	"	8	"
<i>beatitudo</i>	"	8	"
<i>bonum</i>	"	7	"
<i>causa</i>	"	22	"
<i>cognitio</i>	"	19	"
<i>conatus</i>	"	16	"

It should be noticed, however, that some of Spinoza's equivalences do not really help us much to understand what he means. The frequently found expression *causa seu ratio*, traditionally translated as "cause or reason," is an example. It functions today mainly to remind us of the differences in meaning of *causa* and *ratio* in Spinoza's time of vis-à-vis the usages of *cause* and *reason* today.

The strings of equivalences $A \text{ eq } B, B \text{ eq } C, C \text{ eq } D \dots$ are of particular interest from the point of view of simplification and univocality. I shall give an example involving the words *virtus*, *potentia*, *conatus*, *essentia*. The numbers in column 1 refer to the list that appears previously in this article.

Equivalence No.	Found In
53	Part 3, Prop 7, Demonstratio
59	3, P9, Scholium
71	3, P55, Sch
72	3, P55, Cor 2, Dem
91	4, Def 8
120	4, P33, Dem
122	4, P52, Dem
150	4, App 3
174	5, P4, Sch
240	5, P41, Dem
241	5, P42, Dem

From this tabulation it is seen that *virtus* occurs in five different equivalences. These five equivalent expressions are connected with yet others. If the equivalences (except a small number of them) are taken seriously as statements of extensional equivalences obeying the law of transitivity, there is *a possibility of vast simplification of the articulation of Spinoza's system*. If “ $A \text{ eq } B \text{ eq } C$ ” is taken to imply substitutability, new versions of the *Ethics* may be constructed: one in which *A* has been inserted where we now find *B* or *C*, another in which *B* is written where now *A* and *C* occur, and so on. Depending on the way in which the terminological reduction is carried out, one obtains different versions, or reconstructions, of the system.

For example, the terms *power* and *virtue* are connected with several strong expressions of equivalence. There is also an equivalence between *virtue* and *love of God*. In the proof of theorem 42 in part V, it is said that love of God (*amor erga Deum*) is virtue itself (*ipsa virtus est*). Now, if in the *Ethics* we put the term *virtue* wherever we find *power*, we get a text that sounds very Christian and very tender-minded (in the sense of William James). If, on the other hand, we substitute *power* for *virtue* everywhere, we get a text sounding like Machiavelli or Thomas Hobbes, and very tough-minded (in the sense of William James).

The so-called rationalism of Spinoza can be constructed by taking *ratio* as a kind of primitive term and using some of the above equivalences to define other terms in terms of *ratio*. On the other hand, one may start with *amor erga Deum* and use the above equivalences to construct a kind of religious mysticism.

For several reasons, neither of these new texts brings us nearer to the system as intended by Spinoza. One reason is that *few equivalences are intended to be as strong as is required for substitutability*. Another reason is of a still more fundamental character: it may have been Spinoza's intention to suggest that behind, or beyond, a pair of terms said by him to be equivalent there is a single reality that can, and must, be approached through the differing connotations of each of the two terms.

Through the two attributes of extension and thought, human cognition grasps the one substance. Both avenues are essential for human cognition of what “is in itself.” Each of them contributes to this. A limitation on one of them would make human cognition a poorer instrument, even though each attribute is supposed to be a complete expression of substance or God.

In an analogous manner, one may explain the intended functions of many of the theses of equivalence in the *Ethics*. Thus the power terminology refers to a reality that is also referred to by the virtue terminology and the self-causation terminology; yet to restrict the exposition of the system by eliminating the last two terminologies would restrict unnecessarily our apprehension of that reality—so he may have thought.

Whatever the merits of a partial explanation in this vein of Spinoza's use of equivalences, it does not lessen the relevance and importance of an approach by argumentation analysis.

Equivalences as Arguments

The text of the *Ethics* can be seen as a set of answers to questions raised by Spinoza's contemporaries, forcing him to adopt the terminology of his time. The function of Spinoza's equivalences in argumentation may be illustrated by short dialogues between opponents (Op) and Spinoza (Sp):

Op: Mr. Spinoza! According to my religion, a human being may attain a state of glory (*gloria*). You have nothing to say about glory, however, nor does your philosophy permit you to attain glory. What do you have to say to that?

Sp: The glory you talk about *is the same as* genuine self-satisfaction or peace of mind (*acquiescentia in se ipso, animi acquiescentia*). (VP36Sch)

The questioner is thereby referred back to one of the themes about which, in the *Ethics*, Spinoza says a great deal.

Op: I understand what you say about men's love for God, but what about God's love for human beings? In my religion we draw comfort from meditating on a God who loves us. Your philosophy does not permit you to indulge in a loving God, and that illustrates the difference between a warm religion and a cold philosophy.

Sp: "God's love for men and the understanding love of the mind for God are one and the same." (VP36Cor)

SPINOZA

In this last quotation, I have translated *intellectualis* as “understanding” because the term *intellectual* is heavily charged with modern, narrow conceptions of the intellect.

Spinoza’s answer is, of course, not very enlightening for a religious person, but it certainly brings a complex of theological problems—viz., those concerning God’s love of humanity—within the circle of Spinoza’s explicit and carefully worked out philosophy of the third kind of knowing, the intuitive.

Op: Descartes distinguishes clear and distinct ideas from the confused. You seem to presuppose certain criteria of clarity and distinctiveness, for you use these expressions profusely in your *Ethics* without explaining them. Thus your *Ethics* is fragmentary.

Sp: Genuinely clear and distinct ideas are those and only those “that refer to the third kind of knowledge.” (VP28Dem)

Again, Spinoza brings an important range of problems within the circle of those problems that he treats in some detail.

Op: You speak favorably about seeking what is useful to us, and you explain in detail what it implies. What is needed, however, is a similarly deep-founded teaching on how to live virtuously. You lack that: you cannot satisfy those who are striving to attain virtue.

Sp: “The foremost and only principle of virtue or of the right way of living is the search for that which is useful for us.” (VP41Dem)

In this example, it is presupposed that Spinoza has already formulated many propositions on seeking what is useful but that he has not yet formulated any propositions on virtue. Through his answer, he now furnishes his opponents with a theory of virtue. The fight for virtue is a fight for what is “really” useful. As we can see from parts IV and V of the *Ethics*, what is “really” useful in his terminology is such behavior as we today would on the whole classify as virtuous (in the sense of being at a high ethical level).

Now consider the possibility that Spinoza has already formulated, more or less completely, his theorems on virtue, but not those on seeking what is useful. The opponent may then object:

Op: You have lofty theorems on virtue, but as a sympathizer with Thomas Hobbes and a believer in the fundamental principle of self-preservation, I miss a more realistic ethics as part of your philosophy.

Sp: The principle of seeking what is useful for us *is* the principle of virtue and the right way of living. There is no other principle.

Again, Spinoza delivers the goods. He is able to do so because his basic intuitions allow for a vast simplification of metaphysics. He cannot, however, express it through a small number of terms; he *must include all the basic terms of all his opponents and rivals*. Or, not talking in the terms of argumentation analysis, he must include all the important terms of the different traditions and paradigms he is reacting to—in part favorably, saying yes, and in part less favorably, saying “Yes, but . . .” (and rarely, or never, saying no).

He implicitly says “Come to me! Whatever good and true there is in your own worldview, you will find also in my philosophy. Whatever is bad or misleading in your own view, you will get rid of with my help.”

The *Ethics* is a small book about big issues. It ranges over ontology, epistemology, basic physics (between IIP₁₃ and IIP₁₄), basic parts of psychology, some general sociology and pedagogics and, of course, a lot of ethics. Furthermore, it contains theology in the sense of doctrines about God, as well as some sociology of religion and morals.

How was it possible for Spinoza to furnish deep answers to the formidable variety of questions that were *asked* in his own time about all those themes? The question is pertinent because his aim was to convince the people of his own time and his own environment to *change* to some extent their opinions on practically all fundamental problems.

Tentative answer: by means of his theses of equivalence.

One aim of this paper has been to exemplify a combined interest in speculative philosophy and an empirical, “positivistic” analysis of argumentation. The understanding of a great philosophy such as that of Spinoza poses a variety of semantical and argumentational problems. In the above, it has been possible to illustrate only a very special application. It should, however, need little reflection to imagine the possibilities of fruitful applications of, among other things, the various tools mentioned in my article, “A Necessary Component of Logic: Empirical Argumentation and Analysis” (in SWAN VIII).

Einstein, Spinoza, and God

“Einstein and Spinoza” is a tempting theme for a Spinoza scholar and Einstein admirer, as well as for a Spinoza admirer and relativity specialist. In what follows I shall pick out a small part of the many subthemes that today deserve renewed consideration: God, nature, determinism, and timelessness.

When Einstein was invited to contribute to the *Spinoza-Festschrift*, 1632–1932 he declined: “Unhappily love for Spinoza is not enough to justify the writing of a dissertation about him.” Unlike Sigmund Freud, who declined for a similar reason, he added some substantial words about Spinoza’s philosophy. Spinoza was the first, according to Einstein, who “with real consistency applied determinism to human thinking, feeling and action.” He adds that this requires not only consistency in thinking, but also “an unusual purity (*Lauterkeit*), greatness of mind (*Seelengrösse*), and—modesty.” These requirements prevent determinism from being universally accepted among those “who fight for clearness and consistency” (*Spinoza-Festschrift*, 1632–1932, ed. Siegfried Hessing [1962]).

These words attest to the deepness of feeling with which Einstein defended his deterministic outlook. There are, however, many open questions as to exactly what this outlook implies. The word *determinism* has never had a single, fairly definite meaning, and there is little reason to believe that it ever will. In what follows, its relation to concepts of God and essence will be mentioned.

“I have often felt and occasionally also stated that Einstein stands in

This article was reprinted with permission from *Old and New Questions in Physics, Cosmology, Philosophy, and Theoretical Biology: Essays in Honor of Wolfgang Yourgrau*, edited by A. van der Merwe (New York: Plenum Press, 1983), 683–87.

particularly intimate relation to the God of Spinoza.” These words by his old friend and collaborator Arnold Sommerfeld deserve to be taken seriously. “Many a time,” says Sommerfeld, “when a new theory appeared to him arbitrary or forced, he remarked: ‘God doesn’t do anything like that’” (quoted in Schilpp 1949: 103). Taken in isolation, the remark might be used to support the belief that Einstein’s God was a transcendent God, but what he has said and written makes it clear that his God was immanent in nature. This is a cardinal idea for Spinoza. Human beings are genuine parts of nature; therefore, they partake in God’s determining power—however modestly and fragmentarily.

The expression *Deus sive Natura*, “God or Nature,” Nature with a capital N, occurs four times in the writings of Spinoza. It is clear that one must have in mind the distinction between *natura naturans* and *natura naturata* when interpreting this famous expression. It points to Spinoza’s conceptual distinction between an active and a passive aspect of a supreme totality for which he does not have a particular term. God is the name for the active aspect, not the totality.

It seems that Einstein’s feelings concerning harmony and lawfulness *in* nature make a similar distinction relevant. The God of Einstein is not identical with nature or the universe. God is immanent. The immanence is a different kind of relation, a relation difficult to articulate conceptually. Einstein uses the verb *reveal* in the famous cable he felt he had to send as a reply to a cable “Do you believe in God?”: “I believe in Spinoza’s God, who reveals himself in the harmony of all being, not in a God who concerns himself with the fate and actions of men.”¹ God is revealed *in* something, namely, all being, with which he is *not* conceptually identical. On the other hand, God is not *apart* from all being.

Spinoza does not use the term *revealed in*, but prefers *expressed through*. God is expressed through the modes, the particular beings. God is not something apart from these expressions. (This may sound heretical to some Spinoza scholars, but to me it seems to be essential to his system if it is to be understood today.)

The characterization of Spinoza as a “pantheist” is often interpreted in the direction that he identifies God with the universe or the world. Therefore, a better term for his view is *panentheist* (“God in all”). The difference is essential in discussions of the “problem of evil.” That is a still more formi-

dable problem for pantheists than for panentheists. As a panentheist Einstein may have less difficulty in defending his theory of harmony and his maxim that God is sophisticated but not malicious. (Incidentally, interpreting the maxims of Einstein, one should take into account his particular sense of humor. Uttered by a Spinoza, they would carry a heavier philosophical burden.)

Both Spinoza and Einstein leave questions open when talking about harmony, order, and simplicity. Clearly they do not refer to the actual state of affairs, for example, the state of international politics. Einstein says in a letter to C. Lanczos “that the problem of gravitation made him a ‘believing rationalist’: the physically true is logically simple, that is, it has unity at the foundation” (quoted in Holton 1970: 186). This feeling or intuition leads us again to the question of “God or Nature,” *Deus sive Natura*.

That God for Spinoza is not another name for *natura* is seen most convincingly if we put the term *natura* wherever Spinoza uses the term *Deus*. Some places this results in nonsense or at least in statements that Spinoza would not admit as valid. Even when inserting *Natura* with a capital N, there are difficulties. Perhaps Spinoza’s own development from being a young Jewish theologian to a consistent philosopher was never quite completed. Einstein did not undergo a similar dramatic development and might have more easily identified God with Nature.

Does Spinoza’s God not “concern himself with the fate and actions of men”? Human beings share in the double aspect of *natura naturans* and *natura naturata*; they are expressions of God or Nature, and as such are free (*homo liber*) and to an extent determine their fate and actions themselves. There is no God somehow *outside* human beings that might concern himself with men. The power used by a human being who acts, not compelled from the outside, but in harmony with his or her essence, is part of the power of God (*Ethics*, part IV, proof of theorem 4).

The question of power leads us to a second great and controversial area of Einstein’s thought: that of determinism.

As for Spinoza, determinism for Einstein was primarily a belief in order and harmony, as opposed to chance and chaotic antagonisms, not as opposed to causelessness.

Spinoza’s determinism, in contrast to that of Einstein, has often been labeled “rigid,” “absolute,” “merciless.” There are quotations from Spinoza

that support such a view, but if we take part V and the last sections of part IV of his *Ethics* seriously, and not as expressions of inconsistency within his system, these labels must be rejected as misleading. As expressions of God and as partakers in God's power, men are themselves determining their actions. They are creators of something genuinely new. Each thing and therefore each human being "expresses in a certain definite way the Power of God [Nature] by which He [Nature] is and acts" (*Ethics*, part III, proof of theorem 6). Human beings are part of *natura naturata*, but also a genuine part of the creative *natura naturans*. Insofar as their actions are determined by their nature or essence, they are free. Freedom is self-determination. Freedom as determination from one's own nature and essence, rather than from something external, foreign, or even antagonistic to it, is the only freedom rationally conceivable. Lack of determination, that is, chance or arbitrariness, does *not* provide freedom. Our freedom is not secured by a dice-throwing God.

Harmony among people is for Spinoza a consequence of acting freely and not being compelled from something external such as dominating passions. Einstein's unceasing fight against cruelty and oppression seems to imply a belief in the *possibility* of harmony of the kind Spinoza contemplates. The fight was one against irrationality, but Einstein explicitly rejects narrow or pure rationalism in favor of religiosity. For Spinoza there was no problem here: love of God (*amor Dei intellectualis*) is the highest good "we can seek according to the dictate of reason (*ratio*)." Since the time of Spinoza the distance of the meaning of the term *reason* from that of *ratio* has increased. It is now mostly used for what Spinoza would call calculating reason (*ratiocinatio*). Spinoza would agree with Einstein that rationalism in today's sense is too narrow as a basis for fighting cruelty and injustice.

In Spinoza's terminology, freedom and rationality imply harmony with the nature or essence of the actor. The free actions are performed within the framework of laws of nature, not outside. The term *order of nature* is pertinent because as expressions of "God or Nature," the laws are not antagonistic or arbitrary from the standpoint of men, who are themselves expressions of "God or Nature."

Spinoza is, however, eager to eradicate anthropocentric ideas of order and purpose. Man may understand more and more of the laws, as laws of Nature, but doing so implies a gradual dismissal of notions of law arising

from his passive emotions, his original slavery under his passions. The genuine laws do not compel or coerce but make freedom possible.

Sir Karl Popper tried to save Einstein from his determinism, which “amounted to the view that the world was a four-dimensional Parmenidean block universe in which change was a human illusion, or very nearly so” (Popper 1976: 129). Popper wanted him to acknowledge fully “the reality of time and change” and an “open” universe, “one in which the future was in no sense contained in the past and the present, even though they do impose severe restrictions on it” (ibid., p. 130).

It is not entirely clear what Einstein answered in these discussions, but he was scarcely moved in his basic views. The limitation of Popper’s approach owes to his comparing Einstein’s view to Parmenides’ view rather than to Spinoza’s. The latter comparison would hardly have made the discussion simpler, but it certainly would have been more to the point.

Insofar as laws of nature strictly deserve that name, they are in Spinoza’s view eternal. This, however, does not mean the same as that they are permanent in time. Differences in time are *irrelevant*, because these laws are “outside of time.” Consider the expression for π . Even if true, it is not to the point to characterize its validity by saying that it certainly is, was, and will amount to the same 3.14159. . . . Its validity is timeless rather than permanent.

The timeless laws of Nature are like Heraclitus’s law of *logos*: they are completely consistent with universal and pervasive physical change. “You cannot step twice into the same river,” but there is an eternal *logos* in the changing river. Change and time are real, but so are the timeless laws. Without the particular things with limited life span in time, there would be no eternal aspect of reality and no “God or Nature.”

This could be said, so far as I can see, by both Einstein and Spinoza without the slightest difference in basic meaning.

Einstein acknowledged that his proposals in the form of physical theories are free creations of the mind and that his laws, of course, are hypothetical, but he tended to hold that insofar as they agree with the basic laws of nature, the time dimension does not enter. Neither do intrinsic statistical factors.

According to Bohr, he and Einstein had a good-humored dispute about whether Spinoza, if he were alive today, would have agreed with him or

SPINOZA

with Einstein concerning the basically satisfactory character of statistical quantum theories as expressions of physical reality.

If we limit ourselves to the carefulest and most precise formulations of Einstein's negative conclusion, it is difficult to see how Bohr could have argued successfully that Spinoza would have agreed with his view rather than Einstein's. Perhaps, though, Bohr at that time was not confronted with Einstein's carefulest formulations. The latter stress that there is much truth in quantum theories, but as long as there is a basic statistical factor, they are incomplete: a complete theory would have to be nonstatistical—deterministic in Spinoza's sense.

Some Spinoza scholars will interpret Spinoza as Popper interprets Einstein: that the future somehow is contained and determined by the past. Then, however, one misses the emergence of the future through the actions of *natura naturans*, including the actions of the more or less living beings. One need not disbelieve in the *genuinely new* in what happens. There is nothing in the *Ethics* corresponding to the past-present-future mechanical determinism of Laplace. What happens is *not* arbitrary, *not* by chance. From that it does not follow, however, that what happens is contained and (fully) determined by the past.

Einstein sometimes talked as if he believed that human beings are determined to act by forces over which they have no control whatsoever. In an interview he is reported to have said the following—intended to counter-act the overestimation of his own personal achievements:

I claim credit for nothing. Everything is determined, the beginning as well as the end, by forces over which we have no control. It is determined for the insect as well as for the star. Human beings, vegetables, or cosmic dust—we all dance to a mysterious tune, intoned in the distance by an invisible piper.

(Quoted in Clark 1971: 422)

So far as I can see, it is only the complete determination from something distant that here contradicts Spinoza. He stresses our power in shaping events as part of God's or Nature's creative power. Einstein danced to the particular tune of Einstein when he acted rationally (*ex ratione*), that is, acted from "the necessity of our own nature" (*ex necessitate nostrae naturae*). Einstein often seemed to act that way, for example, in the discussion about the completeness of quantum theory!

We as persons muster a power extremely small compared to the total power of Nature; determination from far away is considerable, but not overwhelming: no part of God's power is of zero magnitude, and the specific power of Einstein was and is part of the power of God. "The power of man, as far as it is expressive of his own actual essence, is part of the infinite power, that is, essence, of God or Nature" (*Ethics*, part IV, proof of theorem 4).

Do these remarks solve any problems? Scarcely. The notions of time, timelessness, and determination are difficult to grasp and belong to the ultimate concepts of philosophy. It may be argued that if a philosopher does not grasp what his colleague says in these matters—despite repeated serious attempts at communication—not much can be done except to note this interesting fact. There may be irreducible differences among the "freely invented" (Einstein) conceptualizations through which reason tries to grasp reality.

Is Freedom Consistent with Spinoza's Determinism?

Inconsistency?

Spinoza has been charged with inconsistency in proclaiming both determinism and freedom.¹ Some have put forth weighty arguments against the charge, but the matter is still controversial. Many twentieth-century historians of philosophy have upheld the charge.

In one of the most widely read histories of philosophy, it is simply said that Spinoza denies human freedom. It is also said, however, that he tries to “have it both ways”: to maintain both an extreme determinism and an ethics presupposing freedom (Copleston 1963: 257).

In what follows I shall argue against the thesis on inconsistency and also try to clarify in what sense Spinoza is determinist, in what sense he is not, and *in what sense he did not take a definite stand*.

This undertaking derives its importance from the actuality of Spinoza's teaching, properly understood. I know of no philosopher after Spinoza from whom people can learn as much of significance for our life and community. We therefore need clear expositions of the doctrines of freedom, determinism, and necessity, expositions that do not contain unnecessary philosophical technicalities. In what follows I try to offer one such exposition.

This article was reprinted with permission from *Spinoza on Knowing, Being, and Freedom: Proceedings of the Spinoza Symposium at the International School of Philosophy in the Netherlands (Leusden, September 1973)*, edited by J. G. van der Bend (Assen, Netherlands: Van Gorcum & Comp. B. V., 1974), 6–23. Unless otherwise noted, all translations from Spinoza's Latin texts are by the author.

Determination: Meanings and Kinds

Determination is basically a relation between two relata, the determinans and the determinatum. If A determines B , B may or may not determine A . This holds good whether A and B are different or, in rarer cases, identical. The boundaries of Dutch administrative regions determine each other. We have then to do with a topological determination.

Given the function of whole numbers $y = f_1(x) = 2x$, the choice of x 's determines the y 's. However, we can also write $x = f_2(y) = \frac{1}{2}y$. The relation is symmetric. The choice of y determines the x 's. Or, less voluntaristically and more in the way of ontology, x 's determine y 's and y 's determine x 's.

In this formulation we still use a verb, *to determine*, that suggests a time interval. This we may eliminate in our example by saying that to every and any x there corresponds one and only one y , and vice versa. Time is eliminated. We obtain a key by which to survey in thought an infinitely rich set of pairs of numbers, namely, those satisfying the functions.

Two angles in a plain triangle determine the third. If the two are 30° and 60° , the third is 90° . The third, however, does not determine the other two. They may be 15° and 75° , or both may be 45° . The relation is asymmetric.

In these topological, algebraic, and geometrical examples, time does not enter. We might add a long list of other kinds of examples in which time does not enter.

If "time enters," that is, if A *antedetermines* B , if there is a difference in time, however small, between A and B , the relation is by definition, or by logic of time, nonsymmetric. If A determines B , B cannot determine A . If the ring of a bell determines Mr. Brown's immediate rising from his bed, this second happening does not determine the first happening. On the other hand, appropriate location of a bell may well determine the ring of the same bell if Mr. Brown jumps out of bed, hitting the bell. This only points to the relevance of a proper description of different contexts.

If A determines B and B determines C in time, one may or may not say that A determines C . Some concepts of determination in time are such that there must be time continuity between determinans and determinatum; others admit the possibility of an interval. The latter is the case when we in daily life say that the bell makes Mr. Brown jump out of bed: he may yawn before doing it without falsifying our contention.

Taking antedetermination to be a subkind of determination in a broad sense, we ask, Does Spinoza, when using the terms *determinare*, *determinatum*, *determinatio*, *predeterminatio*, intend to express an antedetermination or other kinds of determination? What can be learned from the many occurrences of the terms in Spinoza's texts, primarily the *Ethics*?

There is perfect agreement among Spinoza specialists that in *some* occurrences timeless determination is intended. Thus, the complete determination and causation of all things by God is clearly timeless. According to the doctrine of immanence of God in the world, or more accurately in Nature, God could not precede Nature, and create it. Further, when he causes himself, he does not precede himself in time.

Let us, however, raise the question "Are *all* occurrences of *determinare* (etc.) in the *Ethics* such that timeless determination is intended?"

At first it seems evident that some occurrences are of antedetermination. Thus IP28 has been largely interpreted to refer to chains of events in time.

In IP28 and its complicated demonstration, however, there is no *direct* reference to time or duration. One thing (*res singularis*) is the cause of another, which in turn is the cause of a third. IP28 would furnish occurrences of *determinari* and *determinatum* in the sense of antedetermination if, and only if, the *determinatum* according to IP28 or its proof follows immediately after the *determinans* in time, or after an interval of short or long duration. There is no direct indication of this, but even if there were a reference to time, it need not be the one-dimensional *historical* time in which each unique limited event starts to exist at a certain date and to vanish at another. The equations of physics contain "t," but they do not contain dates.

We can therefore not without arbitrariness infer from the occurrence of the term *causa* in IP28 that there is a case of antedetermination. The causation may be of one of the timeless kinds, for example, that of delimitation or of giving a reason or ground for something. Or it may be the delimitation of one thing or power in relation to others.

The Infinite Chain of Timeless Causes or Reasons

In IP28 a singular thing is said to have a cause, which again has a cause—not several or infinitely many causes. We thus are led to picture a simple chain of causes—and why not then a chain of events in historical time?

Time is one-dimensional. The most important argument in favor of interpreting IP28 to tell about processes in time stems from this peculiarity. One thing seems to have only one cause, and if so, it is natural to think of something just preceding it. There are, however, many reasons for hesitation.

The cause of a particular thing—its existence and way of operation—is according to Spinoza identical with that through which the thing is understood. The understanding of the cause *contains* the understanding of the effect. The cause of the cause is, again, something through which the latter can be understood. Thus, we have here a chain of causes corresponding to a chain of questions “why?” and “how?” It is not a time chain, however. At least not when we cognize the second or third way.

Time is an *ens imaginationis* and this influences the status of time cognitions.

That through which something is understood has a form of unity through its hermeneutic function. It is therefore not unnatural to refer to it in the singular—as the cause rather than the causes. This may contribute to the explanations of why Spinoza uses “cause” in the singular in IP28.

If *B* is understood through *A*, *A* may, according to common usage, be something existing before *B* in time or it may not. This holds even if *A* and *B* are particular things. Giving examples should be easy, but I hesitate because of the complicated use of the term *res* in the *Ethics*. Is a man, a horse, or a happening a singular thing (*res singularis*)? If a concrete happening or event is a thing, time may not enter in its explanation. “The cause of the increased pressure is the increase in temperature.” Here the increase in temperature does not *precede* the increase in pressure. There is no antedetermination.

Causes are said in IP28 to determine existence and definite ways of operation. The reference to operations in IP28 therefore does not suggest that *causa* as used in IP28 is something determining something that will appear later.

Conclusion concerning IP28: There is in IP28 and its proof no decisive argument in favor of complete or incomplete determinism in time. The determinism may be one of timeless determination, for example, in the sense of lack of arbitrariness or chance.

In *Letter 23* Spinoza says that “all bodies are surrounded by others, and are mutually determined to exist and to operate in a definite and determined matter.” Mutual determination of *A* and *B* occurs when *A* deter-

mines *B* and *B* determines *A*. Here the determinatum cannot follow after the determinans in time; the effect cannot precede the cause. Clearly, Spinoza sometimes speaks about mutual physical determinations that do not make up one-dimensional chains and therefore do not indicate succession in time.

Spinoza sometimes stresses explicitly that “the definite way a thing exists and operates” does *not* refer to duration. Thus, in the preface to part IV, the definite *kind of way* of operation is determined by the essence of the thing, but the essence of a thing does not precede its operation in such a way that after the occurrence of the essence, the thing starts to operate. Determination by essence, if we apply the definition of essence in part II, precludes temporal or processual determination. “The reality, that is, the essence of a thing in so far as (the thing) exists and operates in a certain way, has no relation to its duration.” If the essence determined the operation as a chain of events in time, it would also determine beginning and end, that is, duration. From this I also infer that the determination by essence cannot be in time.

In a chain of events, the event *A* just preceding event *B* may be said to determine the existence but scarcely the operation of *B*. Events do not operate. If a cause *A* determines both the existence *and* the operation of something *B*, *A* must at least have a concrete kind of thing-character, not event-character. The time relation is then either irrelevant or only accidental.

From all this I also tentatively conclude: a complete description of *the way* in which a thing exists and operates does not contain dates. The mutual determinism of all ways of existence and operation is not a determinism in time.

All possible things are, according to Spinoza, expressions or manifestations of Spinoza's God. Perhaps this God is simply not interested in a definite order in time? And Spinoza was perhaps not interested?

Antedetermination and Timeless Kinds of Determination

It is my first tentatively asserted general thesis that what holds of IP28 holds for the *Ethics* as a whole: there is in the *Ethics* not one occurrence of *determinare* (etc.) in the sense of *antedeterminare*—determination in time. More accurately, I assert that there are no *decisive arguments* for the conclusion that *determinare* (etc.) anywhere refer to determination in dated time.

Some formulations by Ernst Cassirer (1920), Harald Höffding (1950), and other highly professional students of Spinoza seem to imply a conclusion in the same vein, but they may not be intended to do so, and their authors have not offered a detailed discussion of relevant evidence in the text.

An objection to the general thesis (the thesis generalized from our conclusion concerning IP28) can be based on a text unit in part II. Spinoza has there inserted a mechanistic physics. He discusses such events as pushing: one body giving another body a push. The first body antedetermines the movement of the second. The second may, in turn, determine the movement of a third.

The proof of the third lemma of this part of the *Ethics* resembles in phrasing and style the proof of IP28. It is, I think, perfectly legitimate and also highly interesting to interpret the more general IP28 in conformity with the more narrow lemma 3. We then obtain an interpretation of IP28 that binds us to a kind of universal determination of durations, which endangers the status of consistency between propositions on determination and propositions on freedom. It is one of my contentions that carrying over such a binding or prejudgment or anticipation from parts I and II to parts IV and V is methodologically unwarranted and harmful. Our conclusion: the determination envisaged in lemma 3 of part II includes complete antedetermination, and its physics of bodies may through an interesting generalizing reconstruction be made to cover the whole doctrine of extension in the *Ethics*. This kind of reconstruction or interpretation, however, is not the only plausible one consistent with the text as a whole.

Among the timeless kinds of determination are some of particular importance for our general theme: (1) Determination in the sense of *delimitation*. Finite things have boundaries, limits that mark them off from other things. Things are defined by such delimitations. "All determination is negation." (2) Determination as emanation. From God as cause and determinans the world emanates according to Jewish and other medieval philosophy that influenced Spinoza. The immanence of *Deus sive Natura* precludes emanation in time. (3) Determination of kind. Anger causes something and something causes anger. That is, the *kind of* affect called anger has certain *kinds of* effects. Or, more nominalistically formulated, members of the class of angers have effects of certain limited differences, thus making up a natural class. Particular things in the sense of particular *kinds of* things have

particular *kinds* of effects or manifestations. Anger, nominalistically conceived, does not precede its manifestations, however.

The third concept of determination, classes of things having classes of effects in common, is particularly important for the theory of active emotions in parts IV and V of the *Ethics*. This theory, again, plays an important role in provoking arguments that Spinoza's theory of determination contradicts his doctrine of freedom through conquering passive emotions.

Let us inspect some determinations of class (genus determination). (a) "The free man . . . tries to join other men in friendship" (IVP70Dem). I interpret this in terms of classes: members of one class of things (*res*), namely free men, cause the establishment of another *class* of things, friendships.

Free men *necessarily* try to establish friendships, they are *determined* to do it, but nothing can be said about a particular free man at a particular date. The essence of free men is such that it determines every member of the class of free men to try to join other men with success or without success. (b) "[H]atred is increased by being reciprocated, and can on the other hand be destroyed by love" (IIP43). Here again, determination *as asserted* by Spinoza is a relation between kinds or, better, between classes of things. Definite ways of operation are asserted, but in the sense of classes of operations forming ways. Details are left out.

Even when Spinoza speaks about *res singulares*, particular things, it is at least sometimes clear that he speaks about particular *kinds* or *classes* of things. This implies that Spinoza is not talking about a strictly singular temporal sequence of events, the one and only one *history* of nature, including man. In that case he would be speaking of strictly singular things at definite *dates*. Of course, Spinoza may have had the opinion that a definite unique singular anger elicited a completely definite reaction. This opinion is not expressed, however. (Moreover, it is false, I think, because the reaction would, for example, also be determined by the level of freedom of the recipient, the customs of his social class, and the physical medium between the angry person and the recipient of the anger. In short, all Nature is involved.)

Laplacian Universes: Not Spinoza's Concern

Datedness becomes decisively important as soon as we by determination think of causal determination à la Laplace. The state of the universe at time

t_0 determines in all details the state of the universe at the next moment $t_0 + d$, where d is the smallest meaningful quantity of time.

We may think of a film played more and more slowly. What happens in the next picture is determined by what we see in the foregoing. With ordinary films, we soon see walking as a series of jumps and jerks, because of the relatively long time interval between the photos taken. The state of affairs at time t_0 clearly does not cause these jumps. The Laplacian view, however, is that the time intervals must approach zero for us to arrive at accurate predictions. Knowledge of the man walking must include knowledge of his position at different times with a millionth millimeter accuracy, forming part of the knowledge of the so-called *Randbedingungen* at the atomic level. Some kings have stumbled and because it has been taken as a bad omen, the miscalculation of millimeters and seconds has great historical consequences.

The development of the universe is one single process in time, and since no pair of macroscopic objects or pair of cubes in spaces are likely to be only arithmetically different, determination cannot be expressed by what happens to kinds or to classes of things. Two grains of sand, or two human beings always subjected to different forces according to where they are, will have different histories and will influence the rest of the universe in different ways. Spinoza's determinism of classes does not suffice to generate a Laplacian determinism.

The Laplacian model of the universe is strange and abstract, but it has with slight alterations (owing to quantum physics) somehow entered the thinking of practically everybody impressed by physics as the source of so-called scientific worldviews.

Even if class determination somehow were completed—the laws of *all* kinds of things being stated—there would still be no way of predicting any future event from the present. Spinoza sometimes uses the term *to predict*, especially in his *Theological-Political Treatise*, but not in any way connected with the question of predictability of world development.² Spinoza does not discuss to what extent, if any, an event can be predicted from something that is determined—the determinatum.

This means that the *Ethics* does not provide or intend to discuss any determinism adapted to physics or natural Newtonian or Bohrian science in general. *To attribute natural science determinism to Spinoza is totally misleading.*

This implies that the discussion concerning the consistency of natural-science determinism with Spinoza's doctrine of freedom is irrelevant. They have never been asserted together.

The determinism of physics is the only form of determination in time (antedetermination) that has been conceptually worked out in detail. The antedeterminism of fate, fatalism, concentrates on a small range of important events such as death, salvation, and marriage. Spinoza perhaps subscribes to that fatalism (cf. VP52). Even if he does, however, this view is very different from general antedetermination. Even if fate orders somebody to die in an airplane crash, he or she can live different ways until death.

It is significant that a contemporary philosopher with exceptional appreciation of Spinoza nevertheless upholds the view that his determinism is of a Laplacian kind. As a consequence, Spinoza's view is criticized as out-of-date.

[M]etaphysical determinism, of which Spinoza was the most uncompromising proponent, no longer seems such an acute issue to philosophers and moralists. . . . The simple faith of Laplace in the theoretical possibility of a complete explanation of every state of the universe is now generally represented as logically absurd. Determinism in this extreme form seems plausible only at a time when the possibilities of complete scientific explanation are accepted as absolutely unlimited.

(Hampshire 1951: 154, 156)

Spinoza was not interested in complete explanations of a state of the universe, and his idea of the vast possibilities of human understanding is untouched by the impossibility of complete explanations of such states.

According to Hampshire, Spinoza adheres to "metaphysical determinism" of a Laplacian kind. He was a child of his age. "[A]n effort of imagination is now required in order to reconstruct the intellectual conditions in which it seemed generally plausible" (ibid., p. 154). If what we have said in the foregoing is tenable, Spinoza has not given us any ("ruthlessly stated") exposition of antedeterminism or of a determinism of events. *His problem was never even similar to that of Laplace.* We do not need to invoke the "child of his age" excuse.

Unhappily, the belief in Spinozism as a sort of inconsistent "mechanis-

tic determinism” colors its reception in a great part of human society: the part in which dialectical materialism is taught.

Spinoza’s Concern: Essential Relations

To get nearer to Spinozistic determinism, we shall proceed from the discussion of determination between kinds or classes of things to the discussion of *relations of essence*. What engages Spinoza are the things that follow necessarily from the nature of the human predicament. As a theoretical starting point we may take what is said in IIP7Dem:

From the given essence of anything there follows necessarily something; but only that is in the power of things which follows necessarily from their definite nature.

Most of the theorems concerning man I take to express what follows from the nature, that is, the essence, of man. Some examples have already been stated above. Others are: “Our mind is active in relation to some things and passive in relation to others: in so far it has adequate ideas it acts with necessity . . .” (IP1). “The acts of the mind originate in adequate ideas, the passions [passive states] depend only upon inadequate ones” (IP3). “Desire arising from joy is, other conditions being equal, stronger than desire arising from sorrow” (IVP18). (The theorem does not assert something about one particular desire and one particular joy, but something about every particular desire and every particular joy. Thus, the theorem asserts something about essential relations between members of *particulars* forming classes.) “An affect cannot be coerced or suspended except through an affect that is contrary and stronger than the affect that is being coerced” (IVP7). “He who imagines himself to be hated by another, and believes that he has given him no cause for hatred, will hate that other in return” (IIP40).

In the last example, the term *imaginari* is of central importance.³ The law of human nature expressed by IIP40 concerns imagination or knowledge of the first kind. Hatred is only an object of knowledge of the first kind. The essential relation expressed by IIP40 is not characteristic of free men who answer hate with love and generosity. If the limitation of IIP40 is forgotten, it is easy to construct a case of inconsistency between theorems in part III and some of the latter half of part IV of the *Ethics*.

Asserted essential relations are asserted relations between *classes of particulars*, not between unique particulars, dated or undated. The particular operation of things *in time* is therefore not determined by essential relations. Durations can, according to the “uncertainty theorems” on the “common order of nature,” only be guessed; cognitions of them are highly uncertain. They are even uncertain *in God*.

Spinoza does not pretend to offer a key to knowledge of particulars in time.⁴ What, then, does he offer us?

Spinoza's important claim is that the way to freedom and salvation depends largely on knowledge of essential relations. His mission is to impart such knowledge to us.

The total set of essential determinants for the person or group or community at *A* causes, under the given conditions, *A*'s decision or action. “What *A* will do,” “how *A* will react,” must lie within a boundary, a limited field of possible actions. Suppose a possibility is actualized that results in a new situation at point *B* within the field. From that point there again is a variety of possibilities within the limits put by essential determinants—and so on, as illustrated above.

Freedom Through Insight into the Determination of Essentials

What we need along our road of increasing freedom is increasing insight into our nature or essence. In particular, we need to know more about our power and its limits. Thus IVP₁₇Sch:

[I]t is necessary to get to know both the impotence and potency of our nature, so that we can determine what we can and cannot do in controlling our affects.

In any situation, what we can do will be many things, not one: a field with boundaries, not a point. The increase of knowledge concerning our nature or essence is an increase of knowledge about (necessary) relations between our essence or nature and that of other things, and necessary relations within our essence or nature. This does not restrict the field but clarifies its extent.

The predicate *necessary* is strictly speaking superfluous because relations within essences or between different essences are not open to external influences. (Modal logic is therefore largely an unnecessary tool.) Necessity

as predicated of the essential relations is by Spinoza opposed to arbitrariness or chance. Necessity is, as he often stresses, not a kind of coercion: necessary is what follows from the very nature of a thing as part of that thing. The necessary partakes in the very definition of the thing. A thing does not coerce *itself*. The term *necessary* would never be used if our insight and our language permitted the presentation of the whole of a thing.

Conclusion: Except for criticizing Descartes's doctrine of free will, or better, *liber arbitrium*, Spinoza does not enter into the debate about antedetermination of the particular consequences of a particular choice. It suffices for him to assert the complete determination of the frame or condition of choices by *the structures of essential relations*. Certain imaginings of philosophers, and of Descartes in particular, must be fought at all cost so that we realize our constitutional limitations (Spinoza the great realist and naturalist!), but the realistic assessment of the limitations must not make man despair on his road toward the greatest heights of freedom and power.

Grades of Power and Freedom

Spinoza does not shrink from talking about what *we* perform or are able to perform: "if we remove . . . an emotion" (VP2); "we form a clear and distinct idea" (VP3); "we have the power of arranging" (VP10); "we are active" (VP18Dem). These expressions are taken from the part dealing with our freedom, but similar expressions are found all through the *Ethics*. We find also a number of exhortations: we must take notice of, understand that. . . . There is no hint in the *Ethics* that this way of speaking sometimes makes Spinoza uneasy. We, persons, members of *Homo sapiens*, are of course able to decide more or less freely to do or not to do such and such. This ability is a necessity of our nature and its recognition part of our insight into essential relations. However, Spinoza's trust in our justification for speaking as exemplified by the above quotations is not shared by all readers—and for good reasons. One of them is the not very clear separation of two concepts, a kind of absolute and a kind of relative freedom and power. Freedom is for Spinoza intimately connected with activity and power.

Definition 7 in part I, the definition of "a free thing," is such that it can apply only to God or substance. In the first part, and also later, Spinoza states, however, that only God is *absolutely* free. This suggests that some-

thing might be free, but not absolutely free. It suggests that Spinoza thinks of freedom as a matter of degree and/or as something we realize in some but not all situations. I shall for the sake of simplicity mostly use the term *degree*. In a few places Spinoza explicitly uses a notion of freedom such that freedom is a matter of degree.

The man who follows reason is more free (*magis liber*) in a state . . . than alone.

(IVP73)

This is the only explicit grading of freedom in the *Ethics*. In *Letter 21* there is another occurrence:

Our liberty is placed not in a certain contingency or in a certain indifference, but in the mode of assertion or denial, so that the less indifferently we affirm or deny something, the more free we are.

Then there is a famous superlative, *liberrimus*, “most free,” in *Letter 58*, quoted earlier in this article, not registered clearly in Boscherini’s excellent *Lexicon spinozanum*.

In *Political Treatise* 2, 7, we find a grading:

The more, therefore, we consider man to be free, the less we can say, that he can neglect to use reason. . . .

This occurrence is of interest also in connecting freedom and necessity: the free man *cannot* neglect reason, he is not *forced* to use reason; but he necessarily uses it, this belonging to his very nature or essence as a free man.

The adverb *libere* is sometimes graded, but perhaps with less relevance for our argumentation. The many occurrences of the expression *absolutely free* (*absolute libera*) and similar expressions with “absolute” are evidence of a broader concept ‘freedom’, with absolute freedom as a special kind or case. Such evidence supports our main conclusions.

Among the free men there may be differences in power, and this makes for, or simply (see IVDf8) is equivalent to, differences in degrees of freedom. According to IVP46, free men strive *as much as they can* to compensate hate with love and generosity.⁵ It is reasonable to suppose that their amounts of power are not identical—but that some have more and others

less. Through the equivalence of gain in power and gain in freedom, this implies differences in degrees of freedom within the class of people Spinoza would consider to be free men in a broad sense.

The combination of a graded use of *free* and the use of expressions like *absolute free* as applied to God, permits us to establish the existence of a broad and a narrow concept of freedom. As a designation of the narrow concept, however, Spinoza sometimes uses simply *liber* without any absolute qualification. It is this usage that gives rise to charges of inconsistency. Man cannot be both free and not-free, at least not under a definite set of conditions, but man *can* be moderately free and therefore moderately unfree. He is both—not absolutely free and not absolutely unfree. This is part of his predicament.

With the establishment of the two different notions, the absolute and the graded, the road is open to eliminate alleged inconsistencies between sentences predicating freedom and sentences predicating lack of freedom.

A series of propositions in part IV, IVP69–IVP73, describe the free man. The way they are talked about strongly suggests that *Spinoza thinks there are free men*. There is nothing hypothetical about them. Spinoza writes in the indicative mood about people “who are ruled by reason” (*Ratione gubernantur*, IVP18Sch) and who “look for what is useful for them guided by reason” (IVP18Sch). On the basis of the above distinctions we take free men to be predominately free—free to a rather high degree, free in fairly numerous important situations or respects. Some assertions on freedom are thus robbed of absolutism, but others clearly are intended to express absoluteness. “That thing is called free, which exists out of its nature’s necessity only, and is determined through itself only to act.” The expression *res libera* in IDf7 is taken to be shorthand for *res libera absoluta*. *Causa libera* in the first part is synonymous with *causa libera absoluta*.

When men are said in IP17Sch to believe they are free, absolutely free is meant. This belief is an illusion, but there are also cases of illusions of non-absolute freedom, as we shall see later.

What Freedom Consists of, According to Spinoza

Spinoza says that freedom presupposes necessary relations and therefore the absence of contingency. When a free agent chooses act *A* in preference to *B*,

the difference in preference must follow with necessity from the nature and striving of the agent and from the agent's insight into the situation. Otherwise, what *is* freedom? There are more or less complete extensional, if not intensional, equivalences between the term *free* and certain other expressions.

In a number of contexts Spinoza says that to be free *is* to follow or be led by reason, which *is*, again, the same as to act out of virtue. To be unfree *is* to submit to passive emotions (affects), to be the slave of (passive) passions. By implication, the free acts from active emotions.

There are other extensional equivalences, based on IVDf8, IVP24, IVP25Dem, IVP26Dem, IVP52Dem1, and IIIP55Dem2. Accordingly, to act freely is to:

- Act in accordance with one's essence
- Act in accordance with one's nature
- Act from the laws of one's own nature
- Do what follows with necessity from one's nature
- Act, and not from contingency or indifference
- Effect what can be understood from the laws of one's nature
- Act from power
- Live according to the dictate of reason
- Conserve one's being according to reason
- Base one's actions on the fundament of seeking what is really useful

To find out exactly what *kind* of relation of equivalence holds at each particular place in the text, one would have to go deeply into the doctrine of definition, essence, and method as suggested, but not elaborated, by Spinoza in *On the Improvement of the Intellect* and other writings. Here it suffices to remind oneself of the inner relations between the term *free* and other terms in his system. It does not work to try to isolate a problem of freedom from the problems of essence, nature, power, reason, active emotion, and adequate ideas. The study of Spinoza is an exercise in systems thinking on the fundamental level.

There is in the *Ethics* nothing hypothetical about free men. The equivalences broaden the relevant places. When in IVP66 Spinoza says that *we*

strive when led by reason to prefer a greater future good to a lesser present, *we* are to that extent free. In the demonstration he uses an analogous expression: “to the extent that we take notice of reason itself.” When Spinoza in the note to the “pessimistic” IVP₁₇ stresses that he reckons with the difference between those who have and those who do not have insight, he by implication points to the moderate or relative difference in level of freedom. The equivalences give the “road to freedom” a richer and more earthbound sense. It is a path we all struggle along, with minor or major lapses. Occurrences of an explicit grading of “free” are rare, but there are many occurrences in which the equivalent expressions are graded. They support our conclusion that the freedom envisaged by Spinoza and applied to human beings is proportional to the extent to which we act from the necessity of our own nature. As in his treatment of common sense, he does not find relevant the question of whether our nature “ultimately” is causally fully determined by something else. The relevance of “ultimateness” only makes sense when we are thinking about time: our nature did not exist before we were born or conceived. If, therefore, we conceive of complete determination as occurring in time, our nature is not ours but a nature prefabricated by something else. Spinoza does not offer such reflections because the determination he talks about is a mutual one, an interdependence. It is only the time dimension that is one-dimensional and gives rise to the thought “I am completely prefabricated.”

The Fictive Human Freedom

If we equate “from necessity” with “not from contingency or indifference,” the necessity postulated by Spinoza says no more than that there is an inner relation between the nature or essence and the acts performed. The acts are manifestations of the nature or essence, and without the acts the essence would be a mere word or fiction. This reveals the dynamic character of the notion of essence (closely related to *conatus*).

Men act from a mixture of causes or determinants, only some of which are internal, that is, follow necessarily from their nature. Men tend to be unaware of the noninternal determinants, the “external causes.” They all tend to believe that they act in such and such a way for *no other reason* than

that they want to act in that way. With this in mind, let us inspect a famous passage in *Letter 58*:

[A] stone receives from an external cause, which impels it a certain quantity of motion, with which it will afterwards necessarily continue to move. . . . Surely this stone, inasmuch as it is conscious only of its own effort (*conatus*), and is far from indifferent, will believe that it is maximally (completely) free (*liberrimus*), and that it continues in motion for no other reason than because it wants to (*vult*). And such is the human freedom which all men boast that they possess. . . .

Absolutely all men? Or all men who boast? Or what? In this letter Spinoza seems in his rhetorical mood to forget for a moment his free men alluded to in part IV of the *Ethics*. They have been said to understand their own actions, and at least some of them have presumably read and accepted what Spinoza says in his *Ethics*! They, at least, clearly did not boast of their so-called *liber arbitrium*.

If, however, we are spontaneously conscious only of our own effort in the sense of our own *conatus*, this explains that we all are *liable* to take internal determinants to be the only determinants of an action. The mistake is one of analysis, and it does not disqualify the spontaneous consciousness of freedom. This consciousness is not a registration of free *will* or of *all* determinants. If we decide to open an umbrella, a spontaneous feeling of free decision governs the act, and we have good grounds for taking this freedom at face value. That the rain externally caused us to do so is irrelevant.

If we have an inclination for analysis, we may take the time to try to list determinants, *including* the external ones. We shall then avoid neglecting the rain, our clothing, our bad health, our cultural determinants, perhaps our conscious vanity, our distaste for polluted sulfuric acid, a slight joy in using our new umbrella, and whatever else. None of these determinants need furnish any arguments against the (nonabsolute) freedom of our action. If, however, we later find that we used the umbrella because of hypnosis or passive affects, we shall arrive at a low estimate of freedom, perhaps a high degree of slavery under passions or a kind of automatism in that particular situation.

The *illusion of freedom* from false analysis is not universal and constant.

SPINOZA

Otherwise, Spinoza's examples would not single out people with weaknesses or those not yet ripe for making a correct causal analysis:

So the infant believes that it freely wants revenge; the timid that he wants to escape. Then too the drunkard believes that, by free decision of his mind, he says those things which afterwards when sober he would prefer to have left unsaid. (Letter 58)

If sober we may freely decide not to say certain things, but this freedom does not reveal *liber arbitrium*. It reflects in action our nature or essence as an integrated personality.

So the delirious, the garrulous and many others of the same sort, believe that they are acting according to the free decision of their mind, and not that they are carried away by impulse. (ibid.)

By "others of the same sort," Spinoza refers to that subgroup of people at a low level of freedom. "Carried away" is another way of describing slavery under passive emotions.

The *illusion* of freedom is, in other words, characteristic of uncritical people, in uncritical moments; it is not characteristic of human beings as such. Some people have *insight into* their own freedom, an adequate idea of their own freedom. The illusion of freedom is not a necessary consequence of human nature or essence, but neither is its absence.

How much people differ from one another, says Spinoza (in IVP66Sch), is clear when comparing IVP18 with IVP66, both of which may be true without inconsistency. The former concentrates on people who are led by passions or opinions, whereas the latter is about people who are led by reason. It is absurd to take what is said about "the delirious, the garrulous and many others of the same sort" to hold about the people led by reason. We could then, for example, derive from IVP66 the following theorem:

Those who prefer a future greater good to a smaller present good believe falsely that they are acting according to the free decision of their mind, and do not understand that they actually are carried away by impulse.

We can as our conclusion subscribe to that of the master himself in his letter to Schuller: "[I]f you will attentively examine my view, you will see

that it is entirely consistent.” We subscribe, but add a qualification: we cannot *see* this consistency, but we can work out a consistent reconstruction on the basis of a set of plausible interpretations. At least, this is what I have tried to do.

Summary Concerning Freedom of Decision

1. The immediate and spontaneous feeling of free choice and decision is a consciousness of our own *conatus*, our basic dynamics, and expressive of our own particular essence or nature. There is nothing illusory about this feeling.
2. The feeling of free choice is sometimes taken to be an indicator of the complete set of determinants of action. From this stems the illusion of complete or absolute freedom, in the sense of absolute self-causedness or total absence of causes.
3. The feeling of free choice is a genuine indicator of internal, not external, determinants.
4. The extent to which we are determined (“internally”) by our nature or essence is a matter of degree. It is never total; it is never zero.
5. The way toward an increased level of freedom, that is, internal determination, is through clarification of our affects, by which means they are converted from passive to active emotions.

General Summary

6. The thesis that Spinoza does not predicate freedom of human beings is false, as is the thesis that if he did, it would result in an inconsistency with his determinism.
7. *Freedom* and *determinism* are imprecise words with a variety of meanings, some of which are such that “*x* is free and *x* is determined” expresses or implies a contradiction, whereas others do not. Among the latter we find those best adapted to the text of the *Ethics*. These meanings have deep roots both in everyday thinking and in the thinking of philosophers before and after Spinoza.
8. Spinoza judges men to be more or less free and therefore also more or less unfree. There is no definite upper limit to human freedom, but it cannot ever be absolute as in God.

SPINOZA

9. The freedom that Spinoza proclaims to be realizable is one that is widely held in everyday life to be realizable: to be determined in our decisions from our *own* nature, from the depths of our soul, from the integrated action of our personalities, and not from pressures, external circumstances, or passions that overrun us; and of course not to act unintelligibly, unmotivatedly, chaotically, unaccountably, blindly, randomly, designlessly. When we judge ourselves free in this sense or these senses, we have not yet asserted anything about how we (since birth?) have developed into what we are: we are not speaking about remote causes *in time*. Neither does Spinoza in his judgment, but he stresses that external determinants are always in operation at any definite time, therefore also at the time of our birth—and before that.

10. Spinoza's determinism is one of essence, *complete determination of essential relations between things*. It is not a determination of particulars, dated or undated; it is not a doctrine of antedetermination. Spinoza does not defend any such doctrine nor does he criticize any. He was not seriously engaged by the problem. What I have attempted, therefore, is only to help a fly get out of a bottle.

Spinoza's Finite God

In interpreting Spinoza there is a trend going back at least to Fichte and Hegel that lets the individual disappear or “melt” in the substance or in timeless being. Kolakowski even talks about a suicide—a murder of self—and mystical destruction of self (*Selbstzerstörung*).

One of the presuppositions of this kind of interpretation is that of taking part I of the *Ethics* as regulative for the other parts. If a proposition of part IV or V is inconsistent with a particular interpretation of part I, the principle of consistency accordingly would demand a change in the latter parts, not in part I. Just as in a system in mathematics, however, one may ask which interpretations in an early part would make a theorem in later parts consistent with the whole.

In part I free/unfree seems to express an absolute dichotomy, God being the only free entity. In the last part, however, some human beings are called free, and freedom and self-determination are predicates admitting more or less. Considering the system as a whole, I have in what follows attributed equal weight to all parts of the *Ethics*. It seems then possible to attribute a high ontological status to particular things and especially to the human person. I shall concentrate on the relation between Spinoza's God and particulars.

First, though, I need to mention certain questions concerning the understandability or availability of Spinoza's system today.

Martial Gueroult's very learned interpretation of part I of the *Ethics* is expressed in a compact text, 586 pages long (Gueroult 1968). If he had been able to cover all five parts, I suspect his text would have run to at least 3,000

This article was reprinted with the permission of the editor, Michel Meyer, from *Revue Internationale de Philosophie* (Presses Universitaires de France) 135 (1981): 120–26.

pages. A great number of difficult terms and passages of part I are explained—but in terms of what?

Unfortunately, the explanans expressions are on the whole no more easily understandable *today* than the explanatum expressions. They primarily give explanations that Spinoza himself might have accepted as in harmony with his own views and terminological preferences, but twentieth-century European readers ask for explanations that both are acceptable in terms of Spinoza's intentions and are, as a whole, understandable today. I am afraid this is asking for too much.

Against this manner of putting it, it might be argued that the way to understand Spinoza's text in its strictly intended meaning is to study the seventeenth-century situation of Spinoza so deeply that, perhaps after many years of concentrated effort, one is, in a certain sense, able to think, feel, and talk like Spinoza. Like many others, I would be delighted to contact such *replicas* of Spinoza's mind. I would attentively study the behavior of such persons in our modern context, and I would of course have innumerable questions to ask.

Unfortunately, I do not see how we could expect wholly understandable answers from such persons. Conceivably, answers would resemble those of Gueroult or other (intrasystemic) systematizations. That would not satisfy me.

Let us for illustration inspect a passage from Gueroult's *Spinoza I*.

Gueroult stresses again and again the incommensurability between the universe, or the finite and infinite modes, and God. Nevertheless, the complicated, carefully written section 7 of his chapter on God as cause, ends with a very simple illustration.

L'incommensurabilité entre l'univers et Dieu n'implique donc pas leur dualité comme êtres extérieurs l'un à l'autre. De plus, elle est ici seulement celle de l'effet à sa cause, et non, comme dans la théologie traditionnelle, celle du fini à l'infini, de l'imparfait au parfait, dont entre eux la proportion est nulle. Il y a, au contraire, sous ce rapport, stricte égalité entre Dieu et l'univers, de par l'identité d'être de la Nature Naturante et de la Nature Naturée, celle-ci étant, tout autant que celle-là, infiniment infinie et parfaite. Pas plus que les modes ne sont *quelque chose de plus s'ajouterait à Dieu*^a, ils ne sont, pris dans leur infinité infiniment infinie, *quelque chose de moins*, en quoi Dieu déchoirait^b. Ce sont véritablement les deux faces de la même médaille.

(Gueroult 1968)

How much am I able to understand of these explanations, even after years of studying the seventeenth century and Spinoza? Primarily that a medal has two faces, perhaps each very different from the other, but nevertheless inseparable from the medal as such and as a whole. Perhaps I have understood how the faces can be faces of the medal without being parts of it—but this is all I understand. The exact status of God, as described in the quoted passage, I do not understand.

Commenting on IP25Sch (part I of the *Ethics*, Proposition 25, Scholium), “God should be said to be cause of things in the same sense as he is said to be cause of himself,” Gueroult says:

De toute évidence, cette thèse n'est concevable que parce que les choses produites, étant tenues pour des propriétés inhérentes à Dieu, sont dans cette mesure Dieu même, si bien que Dieu ne peut se causer sans *ipso facto* les causer elles aussi.

(Ibid.)

The kind of conceivability here asserted by Gueroult is a hypothetical one: “if you know the sense of ‘God causes himself’ (and certain other expressions), then you can conceive that God should be said to be cause of things in the same sense that he is said to be cause of himself.” Mostly, what Gueroult does (and most other experts do) is to assert hypothetical conceivability, understandability of a text unit, presupposing that other units of just as doubtful conceivability for a modern reader are already conceived or understood.

From this I do not conclude that it is pointless to study the text of the *Ethics* or of Gueroult. My quotations from Gueroult I use in defense of a freer attitude toward the text of the *Ethics*. I defend the use of the text to formulate points of view that might not be intended by or even acceptable to Spinoza, but that are based on more or less plausible interpretations of parts or the whole of his system.

One such point of view: the existence, operations, and essence of God *are dependent upon* that of the particular things. Without the existence, operations, and essence of the things, there is no God. IP15I would supplement this point of view with “Whatever exists, exists as a particular thing, and nothing can exist or be conceived without things.”

The Latin word for “thing” should here be *res*, not *modus*. The totality

of things, *Natura*, would constitute the medal envisaged by Gueroult. *Natura naturans* and *natura naturata* would constitute the two faces. The criterion of “*x* is a particular thing” would have to be elucidated, since a usual atomistic interpretation, covering chairs and pens (to mention conspicuous examples from many Western philosophers), scarcely would qualify. The definition should be such that it gives good sense to say that all individual things are “animated in various degrees” (IIP13Sch).

It is instructive that Spinoza has no word or expression for the medal as a whole. The expression “what there is” (or “*omnia quae sunt*”) does not qualify because according to IAX1, all that is either in itself or in something else, is either substance or mode (IP29Sch).

The modes are the expressions of God (cf. IP25Cor, etc.), and without those expressions there is no God. The expressions are caused by God in the same way that God is caused by God. This follows from IP25Sch, the expressions being the same as the things.

Conclusion: the existence, causation, and essence of God are dependent upon the expressions of God.

The dependence relation is primarily a *conditio sine qua non* relation: *A* is a necessary condition of *B*; without *A*, no *B*.

Since causation from God as cause is in general a necessary relation, it is a necessary relation to the essence of each thing. From this it follows that for each thing's essence one may say that without that particular essence there is no God. God's existence, causation, and essence depend upon each particular essence of things.

Now I shall refer to the chief evidence of these finitist interpretations.

In a large important class of occurrences of the term *Deus*, the term is part of an expression *Deus quatenus*, “God as . . .,” “God insofar as. . .” This class reveals that God has two aspects seemingly of equal stature: *Deus modificatus* (“God as modified”) or *Deus non quatenus infinitus est*, and *Deus infinitus*.¹

It is my claim that the text of the *Ethics* viewed impersonally as expressive of a system may be plausibly interpreted as asserting the radical immanence of God in the particular things. The central notion will be “particular thing” (*res*). The things will be regarded from two points of view, that of *natura naturans* and *natura naturata*. These two aspects will be equivalent to the infinite and the finite God. In the system they will be ontologically on

par. This status would make it natural that the finite God, and therefore also the finite substance, were defined after definition 6 (of the infinite God), at the head of part I.

It is largely accepted among Spinoza scholars that Spinoza adhered to some sort of "nominalism." The principle of radical immanence is only tenable, as far as I can see, if combined with a radical form of nominalism. If something has two aspects, only one thing *exists*, but we may need *to talk* about aspects or sides as if they existed independently. A particular coin has two faces, two sides, but there exists only the one coin.

We need to talk about extension, but there exist only particular extended things. The radical nominalism I intend to apply to the text includes nominalism of universals: one may form a class "human beings," but only as a shorthand for a pretended list of all particular human beings.

It is tempting from a certain nominalistic point of view to identify *natura naturata* with the class of particular things and to limit (real) existence to them. One remains closer to the text, however, by taking *natura naturans* as an aspect of the particular things, which all have in common, and *natura naturata* as an aspect that separates each thing from all others. The aspects may be given various names in addition to the above: the substance and the mode aspect, the in-itself (*in se*) and the in-another (*in alio*) aspect, the active and the passive aspect, the self-determined and the other-determined aspect.

The term *aspect* is one of the vaguest, but also the most unpretentious term that can be used in a preliminary characterization of the relation of the finite to the infinite God of Spinoza. The aspects do not exist (separately), but they are there. It is tempting to introduce a consistent terminology at this point, saying that the particular things *exist* whereas the aspects (and other entities on the conceptual level) *intentionally are*. The former have nonintentional existence; the latter, intentional being.

If we use this terminology, *Deus*, both as *infinitus* and non-*infinitus* is, but does not exist. The same holds for substance, attribute, and mode. They all have being, but not existence.

Today, such a distinction may be understood if introduced when one explains geometry. Circular things with a certain, somewhat variable ratio between radius and circumference *exist*, whereas π *is*. All the relations asserted in pure Euclidean geometry *are*, but none exists.

One may speculate about how Spinoza would differentiate verbal utterances that are adequate expressions of the first, the second, and the third kinds of cognition. Perhaps only cognitions of the second kind may be *adequately* expressed verbally. The language would primarily reflect relational insights. The following hypothesis seems to be promising: the language of the *Ethics* is formed to express rational insights, not the particular insights of the third, intuitive mode of cognition. The terminology of the *Ethics*, including terms such as *Deus* and *natura*, should then be looked upon as an instrument for introducing the contemporary reader to a philosophy not entirely dependent on that terminology. The third, and highest, form of cognition is, in this case, not dependent upon the terminology. Perhaps one might even say that the particular intuitive cognitions of the third kind are not adequately expressible through that terminology, or any other.

Conclusion: the terminology of the *Ethics* should be taken as the adequate expression of Spinoza's intuitions.

The immanence of God in human beings is well expressed in IVP4Dem: "The power through which singular things, and consequently human beings, conserve their being, is God's and Nature's power itself . . . , not as infinite, but as it can be explicated through the actual human essence." In the *Treatise on Theology and Politics*, chapter 1, we read, "Our mind . . . contains God's nature objectively in itself, and partakes in it."

In parts IV and V of the *Ethics*, Spinoza introduces gradualist terms of power, freedom, and other basic notions. This lends itself to a gradualist view of "being in itself," "being self-determined," and other predicates expressing the divine component of particular things. The road to freedom is the road toward a maximum of the divine component.

It is my contention that the introduction of the finite God on a par with the infinite opens a way today for understanding a system expressed, but not necessarily intended, by the text of the *Ethics*, and that it may justifiably be termed Spinozist.

Through Spinoza to Mahāyāna Buddhism or Through Mahāyāna Buddhism to Spinoza?

The increased interest in meditation and Mahāyāna Buddhism has resulted in a search for a philosophy that might be understandable in the West and reflect basic insights of the East. A philosophy inspired by Spinoza may be the answer—or one answer.

Jon Wetlesen (1978) has explored this possibility with great acumen. There are, however, pitfalls of interpretation and construction: one may make Spinoza too much the Buddhist or Buddhism too Spinozistic. I do not mean to suggest that this necessarily detracts from the value of the resulting edifice. The comparison of Buddhist versions of Spinoza and Spinozistic versions of Buddhism may lead us nearer to truth.

The Buddhist conceptions of a temporal, instantaneous, or absolute freedom may well be valid, but they do not render the gradualist conceptions less important for life. Sudden enlightenment of great depth must be anchored in a mature, integrated personality, and this entity takes a long time and intensive action to develop.

The distinction between external and internal action is fruitful, but a high level of activeness (causedness through oneself) is possible, and is needed to reach high levels of freedom (understanding, perfection).

The very conception of understanding in the *Ethics* points toward cognition-as-acts in a physical and social environment. Whatever the heuristic and cognitive value of meditation, insight for Spinoza is always

This article was reprinted with permission from *Spinoza's Philosophy of Man: Proceedings of the Scandinavian Spinoza Symposium 1977*, edited by Jon Wetlesen (Oslo: Universitetsforlaget, 1978), 136–58.

insight expressed through an action, a “grasping” (the “lambano-logical” point of view).

Spinoza Between East and West

The practice of meditation has increased by leaps and bounds in the materially rich Western industrial states in recent years. The teachers are on the whole from the East and are exponents of Eastern metaphysical theories. The attitude toward theorizing of those interested in the practice of meditation tends to be rather ambivalent—and for good reasons, as far as I can understand. The amount of woolly, talkative spirituality is staggering, and some excellent teachers of meditation may well be incompetent as exponents of classical Eastern metaphysics.

Persistent and serious practice of meditation, however, leads more or less inevitably to philosophical reflection. It is fortunate that in recent years an increasing number of researchers have combined deep study of the East with a thorough training in Western analytical and other trends. This means that serious practice of meditation in the West can now be combined with, and integrated into, a mature philosophical outlook that makes use of both Eastern and Western sources.

Spinoza occupies a unique position in Western academic textbook tradition. On the one hand, he is trustingly integrated into narrow Western traditions as one of the “great rationalists” of the seventeenth century. On the other hand, deep Jewish, mystical Middle Eastern influence has always been acknowledged by most specialists on Spinoza’s background. Part V of the *Ethics* represents, as far as I can understand, Middle Eastern wisdom par excellence. Spinoza fits in with Eastern traditions in a way that makes it highly unlikely that he can be completely absorbed by any of the major Western trends.

Among the contributions to a comparative study of Spinoza and Eastern traditions, the recent work of Wetlesen (1978) is in many ways outstanding. It combines a thorough knowledge of Spinoza’s system with a not inappreciable acquaintance with meditation and Mahāyāna Buddhism. The work’s greatest merit, however, is Wetlesen’s careful, explicit, and testable use of textual sources.

The result of his work is an exposition of major parts of Spinoza's philosophy that makes it a kind of Mahāyāna Buddhism in a broad sense. Or, if this is too crude a characterization, his work may be said to result in a Spinozistic system closely connected with certain central Mahāyāna texts. The Heart Sutra (*Prajñāpāramitā-hṛdaya-Sūtra*) is one of them (see Conze 1958).

Wetlesen's work is likely to be conceived as a transition from Spinoza to Mahāyāna. My comments argue for a dialectic turn back: Wetlesen furnishes a promising way of incorporating meditational practice and theory in a Spinozistic framework. Mahāyāna Buddhist texts are useful, perhaps indispensable, for this endeavor. In the end, though, the resulting *total view* will be closer to Spinoza's *Ethics* than to any Buddhist text.

Crucial for this turn back to Spinoza is my contention that Wetlesen underrates "*life* under the guidance of reason" and overrates the "tranquillity of meditation." Against "tranquillity" I propose the term *equanimity* as a more central one. Equanimity integrates internal and external balance, and shows itself in contexts of vigorous action. The mode of human nature exposed by Spinoza, as I understand him, is such that it is maximally expressed in the supremely active life—internally *and externally*, insofar as they can be distinguished at all according to Spinoza. In other words, whereas Wetlesen's Spinoza in the last analysis is markedly otherworldly and tender-minded (in the sense of William James), as I see him he combines marked this-worldly and tough-minded aspects with obvious tender-minded traits. The combination is highly precarious, but the system of Spinoza *is* highly precarious: its pretension is extreme insofar as it tries to address everything of lasting value in every major tradition, East and West, even when the values seem mutually, utterly inconsistent.

Freedom₁, Freedom₂, Adequate Cognition, and Internality

Wetlesen distinguishes two conceptions of freedom, and two ways of freedom. Freedom₁ is absolute and there is no "way" to it in the sense that it is "already there." It is the "highest" kind of freedom. Freedom₂ is relative and gradual. It takes time and effort to reach high levels of freedom₂. There is, according to Wetlesen, no continuity between these freedoms. Freedom₁ cannot develop from freedom₂. Some quotations will make his point clearer.

SPINOZA

I believe that we must distinguish between two fundamentally different ways to freedom in the philosophy of Spinoza. Borrowing from related conceptions in Indian and Chinese philosophy, especially from Mahāyāna Buddhism, I shall call these two ways the gradual and the instantaneous strategies of liberation. For the greater part, this distinction is not made explicit in Spinoza's own exposition. . . . In some crucial contexts, however, he draws the distinction explicitly. If the former contexts are read in the light of the latter, we shall have an interpretation of Spinoza's ethics of freedom along the lines that I attempt to reconstruct here.

Spinoza appears to imply a distinction between two kinds of internal freedom, one absolute, the other relative. Internal freedom of the absolute kind presupposes an intuition of oneself and other beings in nature from the viewpoint of eternity. This cognition cannot be approached through a gradual strategy, since approximation presupposes a process of time, while the viewpoint of eternity has no relation to time, but is incommensurable with it. Nor is there any need for such an approximation, as this intuition is already there, constituting the very essence of the mind. The act of becoming conscious of this can, in one perspective, be described as a sudden enlightenment. From another perspective, however, the notion of suddenness is also seen to be misleading. For the enlightened person sees that freedom, in the absolute sense, consists not in becoming something that he is not, but in being what one is from eternity. As Spinoza says in the passage above, the sage is conscious of himself, of God and of things by a certain eternal necessity. The difference between the sage and the ignorant is therefore above all a difference in self-awareness.

(Wetlesen 1978: 3–4)

One of the trends of argumentation supporting these conclusions is based on Spinoza's theory of affects:

On applying the gradual strategies of liberation, a person may counteract those passions which are evil by means of other passions which are less evil, or which are good. Still, however, these antidotes are passions, and therefore the result will not be freedom in the absolute sense, since this requires that the strategies are based on actions. From this it seems to follow that freedom in the absolute sense cannot be achieved by means of a gradual strategy. This confirms once more what I said above concerning the relation between the gradual and the instantaneous strategies. Only the latter lead to freedom in the absolute sense, and are therefore more fundamental than the gradual strategies.

(Ibid., pp. 6–7)

Another trend takes account of the “internal” character of adequate cognition:

If Spinoza’s conception of adequate cognition is related to the viewpoint of eternity in the manner I suggest, then it seems reasonable to suppose that his conceptions of action and freedom must be primarily of an internal kind. The freedom of the sage consists in his power to conserve his being in this type of adequate cognition. His conation and cognition are adequately determined from within.

(Ibid., p. 24)

The concepts freedom₁ and freedom₂ are introduced using the above conceptions of actions and adequate cognition:

When action is determined from within the way mentioned, it can be called free in an absolute sense. It is not contingent upon external conditions. It pertains to man as an eternal being. I shall call this freedom₁, and its contrary, which pertains to man as a temporal being, I shall call bondage₁.

In addition to these conceptions Spinoza appears to have recognized a second kind of freedom and bondage, which may be called relative. They pertain to man as a temporal being, and relate to the degree of autonomy or heteronomy which a person may have in relation to his external environment. I shall designate these as freedom₂ and bondage₂. They are subspecies of bondage₁.

(Ibid.)

It is important to note that Wetlesen associates externality with external environment, which includes other people, society, political institutions, and so on.

What the human condition really is, can only be understood from the viewpoint of eternity. To be ignorant of this viewpoint, is to be under bondage in the most fundamental sense, while to be aware of it, is to be internally free. This seems to be the foundation of his perennial wisdom.

(Ibid.)

It seems (anticipating some criticisms) that Wetlesen identifies the absolute freedom of Spinoza with an intuitive insight of a very special kind (*not* identical with the third kind of cognition in Spinoza’s terminology). The third kind involves interaction with the environment—for example, behavior toward friends, making a decent living, polishing lenses.

If a concrete person living in a particular society is to be characterized as *being* absolutely free, this should characterize his total life. If the crucial *insight* is an isolated mental act of a person who otherwise, that is, in regard to freedom₂, acts more or less as a slave, why should this person get the fabulous title of absolutely free? One of many basic questions is, *Does Spinoza consider it possible to be free₁ without being on a high level of freedom₂*? If so, why call freedom₁ a *higher* freedom? What is particularly high in a person living like a slave? On the other hand, if freedom is indispensable, it takes time and effort to reach freedom₁. Essential to Wetlesen's *definitions*, however, is that freedom₁ is there all the time, that is, even at a very low level of freedom₂.

Put crudely, I doubt that Spinoza would accept any ideal or model of a free human being that is consistent with a low degree of freedom₂. His description of people on a low level of freedom, his "slaves of passion," tyrants, people reacting with hatred, without generosity, and so on, does not suggest that he would call them free in *any* sense. Or if he would do so, he would mean a potential, not actualized freedom.

Equanimity or Tranquillity?

The equanimity characterizing the free human being may be conceived either in terms of meditative tranquillity or as a basic steadiness in the face of the external strains and stresses of an active life. For example, a statesman (like Johan de Witt), a leader of an expedition through the jungle (like Livingston), or a *karmayogi* like Gandhi may have a high or a low degree of equanimity in "external action." Does Spinoza think of the sage as a meditative rather than a socially and otherwise active person? Wetlesen's interpretation goes in the first direction. I shall *argue* for the latter but not dogmatically assert its greater historical accuracy or correctness. The interpretation of Spinoza is an endless task.

My main argument is, paradoxically enough, inspired by the same variety of Mahāyāna Buddhism as is Wetlesen's: the teaching that the farther along the path to supreme levels of freedom a human being proceeds, the greater the identification and compassion and therefore the greater the effort to help others along the same path. This implies activity of social and political relevance. Gandhi, considering Buddhism to be a reformed Hin-

duism, furnishes a good example. His mistakes were many, but he tried through meditation of sorts (combined with fasting) to improve the quality of his action, especially his consistency in maintaining a broad and lofty perspective. He deplored the followers in his ashrams who spurned outward action and concentrated on metaphysics, meditation, and fasting. He conceived that as a kind of spiritual egotism. He did not recognize yoga meditation and prayer as an *adequate* way to insight, perfection, and freedom. Advance toward the highest levels requires interaction with the terrifying complexities of social life.

It is not against anything in the *Ethics* to suppose that *understanding acts*, cognitions internally joined with active affects and constituting interactions between body and environment (under the attribute of extension), are complex and comprehensive, like gestalts of higher order. Examples are highly complex projects such as writing the *Ethics*, preserving and deepening friendships, acting as a mentor or guru, administering a large monastery. As to the last gestalt, see the in-many-ways instructive *Born in Tibet*, by Chögyam Trungpa (1971).

If carried out in the spirit of eternity, the high level of “external” activity necessarily differs from that of a busybody. Retreats and meditation *may* be necessary in some cases, but this does not imply *tranquillity*, only concentration and equanimity. Wetlesen writes in a slightly different vein, it seems:

In the first place, it seems to be necessary for the person to be able to arrange his life in such a manner that he achieves certain periods of contemplative tranquillity. This, I believe, is implied by 5P10:

5P10

As long as we are not agitated by affects which are contrary to our nature do we have the power of ordering and connecting the affections of the body according to the order of the intellect.

Actually, two conditions are involved here: The person must achieve tranquillity in the sense of not being agitated by those affects which are contrary to his nature; and he must be able to understand things according to the order of the intellect. The first of these conditions requires, I suppose, that certain periods of seclusion must be set off for interior recollection, these being perhaps what we might call a sober type of mystical contemplation. At any rate, it will not do to be a busybody all the time. A certain detachment from temporal concerns is required now and again.

(Wetlesen 1978: 377)

All this may be reasonable from a *pedagogical* point of view, as good advice from a guru. It will not do to be a busybody *anytime*. Activeness in the sense of Spinoza, however, requires integration and concentration, not tranquillity. Gandhi prayed and meditated even during hectic political meetings.

Spinoza's theory of the second and third kinds of cognition does not rule out the person's ability to uphold the point of view of reason and of eternity when acting "externally" in a social environment. Ideally the "free man" may do this *without* retreats to meditation and social isolation. My point is one of principle, not at all meant to weaken the pedagogical importance of these interludes or what Wetlesen would call the strategy of retreats and meditation. These are means, however, not ultimate needs.

The Complexity of Intuition

Freedom₁ is adequate intuition of oneself and other beings in nature from the viewpoint of eternity as appears earlier in this article. More explicitly, "the highest freedom consists in an adequate cognition of man's own essence and existence through the essence and existence of God as his immanent cause."

Even if this insight is intuitive and in a sense eternal (which is difficult to grasp and convey in discursive, argumentative thought and articulation), I cannot see how it is something instantaneous. It is an extremely complex intuition, and we know from personal insights that such intuitions have a depth dimension.

Our first acquaintance with irrational numbers or Godel's theorem makes us perhaps use correctly some definitions and makes us capable of solving certain problems, but our depth of intention improves only slowly over years of study. There is an abyss of depth in everything fundamental. Moreover, structure persists even if we have the feeling of touching something absolutely simple.

My conclusion is clear: I cannot believe in the instantaneity of the intuition of freedom₁, nor in its lack of an improvable depth dimension.

Internality Implied by Absoluteness: Totality and Part

The requirement to act *in the strictest sense* from the laws of one's own nature, *only*, or to be *completely internally* caused seems to be satisfied only by God.¹

As Wetlesen (1978: 30) points out, however, Spinoza certainly admits that some human beings are freer than others:

Should we conclude, then, that according to Spinoza, *freedom* is beyond the reach of man, and that it is the privilege of God alone? In a certain sense, this may well be what he means. Nevertheless, it must be interpreted in the light of other passages where Spinoza positively affirms that men may be *free*. I have already quoted 5P42Sch, where he contrasts the sage and the ignorant, and implies that the former enjoys freedom of mind. In 4P37Sch he draws a similar contrast between the truly virtuous and the impotent person, and in 4P66Sch between the free person and the slave.

Wetlesen adds a number of other quotations from the *Ethics*. I think one may safely assume that Spinoza thinks there are comparatively free human beings. Are there, however, *absolutely* free human beings? Yes, concludes Wetlesen. The argumentation is complex and precarious. It calls for somewhat extensive quotations.

God is absolutely infinite, and as a consequence is present in all his effects, and equally present in parts and wholes (cp. 2P45Dem, 46Dem).

For this reason the singular things in *natura naturata* cannot be separate substances. They are not really distinct from each other, but only modally; internally they are related to one another through their common immanent cause, God. In so far as a singular mode, such as a human being, cognizes himself and other modes in this manner, can he be absolutely free.

(Wetlesen 1978: 31)

One of the decisive points in this difficult argumentation seems to be that God expresses himself *totally* in every part or mode. “Totality” is also decisive in the following elaboration:

And when a singular mode is cognized through God as its adequate cause in this way, it is adequately cognized. This cognition embraces in one single grasp, as it were, the totality of those causes which generate the thing. Through this cognition a person can be said to internalize the immanent causality of God, and thereby to participate in the absolute freedom of God. . . .

Spinoza’s philosophy should therefore be considered as panentheistic, rather than pantheistic. However, in so far as a human being cognizes himself and other modes through their first cause, and sees that this is an immanent and free cause, and that it is infinite, eternal, and indivisible, he feels and experiences

SPINOZA

that this cause is totally present in himself, and equally present in the parts and in the whole of himself, and consequently he participates in its freedom.

(Wetlesen 1978: 32)

This freedom is absolute, but according to Spinoza, God does not share it with the modes—in spite of his immanence. We are therefore not closer to Wetlesen's freedom₁ in spite of his important interpretation of totality.

Gradual Approach Necessary in Life

Wetlesen is, of course, aware of 4P4:

It cannot happen that a man should not be a part of nature, and that he should be able to suffer no changes save those which can be understood through his nature alone, and of which he is the adequate cause.

(Quoted in *ibid.*, p. 29)

If this is so, how can a human being be an absolutely *sole* cause of an action and a result of the action? Wetlesen uses his distinction between internal and external effects:

For even though it is impossible for a person to be an adequate cause of an external effect, he may be so of an internal effect. In that case the effect is internally determined by the nature of the agent, in so far as his nature is internally determined by God (cf. 5P30&Dem, 31&Dem). As Spinoza says in 4P68Sch, this may take place “in so far as we regard human nature alone or rather God, not in so far as he is infinite, but only in so far as he is the cause of man's existence.” We should read this in the light of 2P45Sch: “For although each singular thing is determined by another singular thing to exist in a certain manner, yet the force by which each of them perseveres in its existence follows from the eternal necessity of the nature of God (see 1P24Cor).”

(*Ibid.*, pp. 32–33)

It seems that *a person*, according to Wetlesen, may remain in a state of absolute freedom provided all his acts are internal:

What kind of effects is it that such a free person can produce? I have already suggested that these effects must be purely internal, but what do they consist of? The answer, I believe, is to be found in this direction: If a person *cognizes* himself and all things adequately through God as the adequate and internal

cause, then the person will have a power to determine his further cognitions in such a way that they maintain themselves on this adequate level (2P40, 5P41&Dem). This cognition, moreover, will engender active affects, such as the intellectual love towards God (5P20Dem, 32Cor, 33Sch, 36Sch), and these active affects will be sufficiently strong to counteract the passions, and thereby to liberate the person from his bondage (4P20Sch, 38, 40, 42). I quote:

5P20Sch

From all this we easily conceive what is the power which clear and distinct cognition, and especially that third kind of cognition (2P47) whose foundation is the very cognition of God, can do with the affects, namely, that if it does not remove them entirely in so far as they are passions (5P3, 4Sch), at least it brings it about that they constitute the smallest part of the mind (5P14). Moreover, it begets a love towards an immutable and eternal thing (5P15) of which we are in truth partakers (2P45), and which therefore cannot be debased by the vices which are in common love, but which can always become greater and greater (5P15), and occupy the greatest part of the mind (5P16) and deeply affect it.

(Ibid., p. 33)

The quotation from Spinoza and the interpretation by Wetlesen confirm, as far as I can see, that a person can *reach* a continuous level of absolute freedom only gradually, turning passive affects into active. There is an ambiguity here: something is instantaneous and the person “has” it all the time, even if not aware of it, but there is also something that is gained gradually—I would say: gained through gain in freedom₂.

Let us study the terminology in the following conclusion:

From the interpretation set forth here we may conclude, then, that absolute freedom is possible for man, but only to the extent that his actions have internal causes as well as internal effects. This is a complete self-determination, and therefore a freedom of the type which I call freedom₁.

(Ibid., p. 34)

Seen from noneternal points of view, a person lives in time, and to say about a person that he or she is absolutely free would mean that he or she *remains* on a level of absolute freedom whatever the cognitions required. But some actions certainly have external causes or effects. Therefore, a person cannot be absolutely free. On the other hand, a person may maximize purely internal actions, and thus we get a graded notion of absolute freedom. In the terminology of Wetlesen, we would add to the last quotation:

A person increases his or her level of attainment of freedom₁ if, and only if, the extent to which his or her actions have internal causes and effects, increases.

Here freedom₁ *as a concept* is not subjected to grading, but a person's *attainment* of freedom₁. The latter is the more important if we wish to *gain* freedom.

The impossibility of the gradual approach as a *sufficient* strategy to reach absolute freedom should be distinguished from the possibility that such an approach is a hindrance to reaching freedom₁. Wetlesen seems to think that a person who strives to reach higher levels of freedom₂ ipso facto cannot reach freedom₁. The person must stop trying! This might be good Buddhism, but is it good Spinozism?

[W]e may conclude that as long as a person strives to attain the ideals of his imagination, he will fail to attain freedom in the absolute sense. It makes no difference what kind of ideal he holds up for himself. . . . However, as long as a person adopts such an exemplary model as an end to be achieved in the future, he will be bound to a process of time. He may be freedom-bound, perfection-bound, intellect-bound, love-bound, and so forth; but in any case he will be time-bound. Therefore he will not be free in the absolute sense defined in 1D7, since that requires emancipation from time-binding.

(Wetlesen 1978: 388)

If previous comments are tenable, the likelihood that a person reaches conscious freedom₁ *increases* with increasing level of freedom₂. There are no purely internal actions—the mind is not a container of acts; all acts are explicitly or implicitly environmental. At least, I cannot see how Wetlesen has succeeded in establishing his concept of purely internal acts.

It seems that Wetlesen has not always distinguished conceptual problems from life problems where that needs to be done. Personal problems are always “in time,” and therefore also *applications* of any concepts whatsoever to persons. The concept of eternity must be kept distinct from the criteria for determining whether a person *has* attained the viewpoint of eternity and *when*. It must also be distinguished from the criteria for determining to what extent this viewpoint has been attained. However, all this need not affect the *concept* of eternity. The concept can be retained in its nongraduated form.

Suppose a person has maximally attained the viewpoint of eternity. He

or she will nevertheless, if a *karmayogi* or a bodhisattva, act, with increasing understanding, in the temporal environment and thus carry out cognitions in part based upon the activity of the imagination.

Perhaps this is completely in agreement with Wetlesen's conceptions, but then the above quotation from his work is misleading.

Absolute Freedom Through Cognition Only of Our Own Mind; Closeness of Mind to God

From this closeness of mind to God, Wetlesen proceeds to argue for freedom or even salvation through cognition of oneself alone:

The highest freedom of man, which is nothing else than his salvation, consists in an adequate cognition of his own essence and existence through the essence and existence of God as his immanent cause (cp. 5P36Sch).

(Ibid., p. 75)

The evidence of 5P36Sch does not corroborate Wetlesen's thesis very strongly. Adequate cognition of one's own essence and existence is a time-consuming thing. We have to understand our passions and transform them into active emotions like generosity toward those who hate us.

It is no easy affair even to find out that an affect we have is not active, but passive. One of the ways is orthodox psychoanalysis. It is not possible, or only very rarely possible, to carry through such an analysis alone. There are other methods, but no shortcuts, it seems. God has *not* provided shortcuts. Wetlesen's strategy of attainment of freedom₁ is said to be instantaneous, but it seems to imply that we arrive gradually and painfully at a clearer and clearer understanding of more and more of our affects. It is not done in a general way, but with each affect taken separately. Wetlesen cites

Spinoza's ways of formulating the first two remedies against the passions, which he summarizes in 5P20Sch. The first step consists in this:

5P20Sch

It appears from this that the power of the mind over the affects consists:

1. In the cognition itself of the affects (5P4Sch).

That is to say, it consists in a reflection on the cognitive and affective acts, thereby forming a clear and distinct idea of them. The second step, moreover, is described in this way:

5P2oSch

2. In the separation by the mind of the affects from the thought of an external cause, which we imagine confusedly (5P2 and 4Sch).

When cognitive objects, as well as their affective coloring, are seen in this way, they are no longer hypostasized as external ontological realities, that is to say, they are not assumed to be transcendent things, but are seen to be projected by the consciousness itself. Furthermore, they may be understood through their immanent and adequate causes, and thereby cognized adequately. At this point, however, we move away from the phenomenological attitude of Husserl and into the ontological attitude of Spinoza. But this kind of ontology has nothing to do with the assumption of external objects. It consists in seeing all modes as the effects of the immanent causality of God. When a person has attained this degree of self-knowledge, his faculty of imagination is free, as Spinoza says in 2P17Sch. It then depends on his own nature alone. He lives entirely in this immanent field of his transcendental consciousness, as Husserl would say. He is mindful that his life-world is constituted through his own imaginations and affects, and through this awareness he neutralizes the binding effect of his own projections, thus remaining internally free.

(Wetlesen 1978: 361–62)

What is not convincing is that the “seeing *all modes* as the effects of the immanent causality of God” (my italics) can constitute one single set of seeing. What about our own passions, race prejudices, ambition of understanding Spinoza? We certainly do not have the ability instantaneously to understand *each* of the passive affects so that we get a clear picture of their origins—and not just a *general notion* of their dependence on natural laws and God as their immanent cause. Spinoza scarcely recognizes *general* knowledge of passions as a liberating force. Passions as “confused ideas” are not turned into clear ones wholesale. This implies gradual, not instantaneous freedom. The belief in sudden, definitive illumination of the life-world (*Lebenswelt*) goes against the realism of Spinoza and his critical attitude toward revelation in religion and otherwise.

Enlightenment Happens in Time, but Does Not Develop out of Nonfreedom

The instantaneity of absolute freedom gets to be somewhat mystical in a bad sense if we cannot say that a person attained it or attained conscious-

ness of it at a definite time or within a definite time interval, for example “sometime between ages x and y .”

[W]e must beware of not construing the transition from bondage to freedom as a transition from inadequate cognition and passive affects to adequate cognition and active affects as if the latter emerged at a certain moment of time. For it is impossible that the latter could develop out of the former (cp. 2P41 and 5P28, together with 3P1 and 3). If adequate cognition and active affects can be actualized in a person at all, they must be potentially there from the beginning.

(Ibid., p. 389)

That something develops *out of* something else is a much stronger assertion than that the one was a necessary condition of the other. Beethoven’s music was a kind of necessary condition for Schubert’s music, but genuinely new things are present in the latter. One cannot say that what Schubert did developed *out of* what Beethoven did. Adequate cognition of something may emerge *after* degrees of inadequate cognition “of the same,” and thus be fixed in the time order, without our assuming that the adequate *developed out of* the inadequate, like an adult from its imago.

A person undergoes development in time. There is a transition from one phase to another. New traits form; old ones vanish. One kind of transition is from a lower to a higher level of perfection; it is at the same time a transition to a higher level of freedom. This transition is also a transition to more adequate cognition and more active affects.²

We cannot understand the development of a person except by taking into account many parts of the body and many parts of the mind, and only when considering the person as a part or fragment of Nature. Thus, I agree that adequate knowledge does not develop *out of* inadequate. The further inferences made by Wetlesen on the basis of this insight seem unwarranted, however.

Writing about the absolute freedom to an audience that has not attained, or is not conscious of, absolute freedom presupposes that attainment of such (conscious) freedom *happens to a person*—that is, can be fixed in time. This does not exclude that the writer and the audience later agree that the time dimension is irrelevant or unreal. Having attained and retained that view, they are then clearer about the view of eternity. This state of affairs cannot be anticipated, however.

In the following passage Wetlesen makes a concession, it seems, in the direction of the above remarks.

So also may the viewpoint of eternity suddenly break forth to the conscious awareness of the mind, calm and clear, when the hindrances are removed.

When this enlightenment has been attained, the person will know that in reality, and from eternity, he is free in the absolute sense. His freedom, in this sense, is an eternal truth and absolute necessity. However, if this be so, then it implies that he must reevaluate his former conceptions about himself and about the human condition in general with regard to bondage and freedom, as well as the transition from the one to the other. . . . In so far as he cognizes the whole situation adequately from the viewpoint of eternity, he knows that his portrait of himself, as presented by the imagination and the memory, in a certain sense is an illusion. It does not tell what he really is, and is nothing but a mode of cognition, or an entity of the imagination.

(Wetlesen 1978: 390–91)

The viewpoint of eternity “may suddenly break forth,” that is, sometime *within* the time order. When this viewpoint gets to be conscious, the biography of the enlightened person looks quite different. This can be understood. The points of reference will be different—“all” will be different. It might be compared to what happens after a religious conversion, or when a person rather suddenly moves from communism to anticommunism (Koestler and others). I think it is important to concede this, and to stress *discontinuity*. There is a “jump” in the Kierkegaardian sense, or in a sense related to his.

All this may be conceded. Its relation, however, to Spinoza’s conception of freedom remains unclear—unclear, to me, both in the use of the term *absolute freedom* and in its status as “higher” than any freedom attained gradually. The formulation “The person *P* is eternally, absolutely free and has never been otherwise” is an unhappy one outside Buddhism. The quotations from Spinoza that Wetlesen uses to support such a formulation are compatible with the decision to leave it out. 5P31Sch is compatible with the theory of gradual enlightenment:

The stronger every one is in this kind of cognition, the more he is conscious (*conscius*) of himself and of God, that is to say, the more perfect and blessed he is, which will appear still more clearly from the following. Here, however, it is to be observed that although we are now certain that the mind is eternal in so

far as it conceives things from the viewpoint of eternity, yet, in order that what we wish to prove may be more easily explained and better understood, we shall consider the mind, as we have hitherto done, as if it had just begun to be (*tanquam jam inciperet esse*), and had just begun to understand things from the viewpoint of eternity. This we can do without any risk of error, provided only we are careful to conclude nothing except from clear premises.

(Quoted in *ibid.*, p. 391)

Conclusion: the absolute freedom₁ is foreign to Spinoza's system.

Wide and Narrow Concepts of Grading

The distinction between graded and ungraded calls for some clarification. A grading *need not be continuous*. Hardness of minerals is graded—for example, “scratchable with a fingernail,” “scratchable with a steel knife,” “scratchable with a diamond.” A person may be said to gain in rationality when he or she behaves rationally in more kinds of life situations, and is less rational in none. There is not, however, a continuous transition from one situation to another, from one behavior to another, or from an inadequate cognition to another inadequate one, or to an adequate one. There may be abrupt changes, wild leaps. Nevertheless, a person may be said to develop and change gradually. The transition may be discontinuous and there may be only two grades.

Either a cognition is adequate, that is, complete, or it is inadequate, that is, incomplete or not complete. If absolute freedom is correlated with adequate cognition, and its contrary with inadequate cognition, it would seem to follow that the distinction between freedom and bondage must also be dichotomous.

(*Ibid.*, p. 395)

Here it seems that Wetlesen does not distinguish between conceptual relations and life relations. A conceptual dichotomy does not itself permit grading—this is true by definition—but as soon as it is asked *to what extent* a person cognizes adequately or inadequately, a grading is possible. Spinoza uses grading, this in spite of a rigid nongradual distinction between adequate and not adequate. There is also a place for grading the clarity, depth, and other characteristics of *an act of* adequate cognition. Grading is accepted here by Wetlesen himself:

SPINOZA

[I]t may be possible for a person to be more or less conscious of the adequate cognition which constitutes the essence of his mind from eternity.

. . . we may speak of degrees of freedom₁ after all, these degrees being in a one-to-one correspondence with the clarity of the conscious awareness which the mind *has* of the adequate cognition which it from eternity *is*.

(Wetlesen 1978: 395–96)

In his argumentation, however, Wetlesen sometimes tends to adopt or imply narrow conceptions of grading. For example, in the following quotation grading seems to imply a quantitative element. Grading, though, is an ordering of qualities. Wetlesen himself says that freedom₁ is *higher than* freedom₂. The distinction between first, second, and third kinds of knowledge involves (among other things) a grading. About the third, Wetlesen says:

However, not all persons are conscious of it, and those who are, do not have an equally clear and distinct idea of it. This degree of conscious awareness and clarity brings in a quantitative element, which makes it possible to talk about degrees of freedom after all. However, in this latter case we talk about degrees of freedom₂, and not about degrees of absolute freedom, which would sound rather queer in any case.

(Ibid., p. 396)

What Wetlesen says here about gradual strategies suits a rather narrow concept: a “quantitative element” makes it possible to talk about degrees. In part because of his tendency to associate degrees with quantification, he attributes negative characteristics to the “gradual strategy of liberation.” Such strategies, however, require *wide* concepts of grading, concepts in which discontinuities are not excluded. Higher levels of understanding do not develop “out of” the lower. New qualities appear abruptly.³

Spinoza’s Way and Buddhist Meditation

Wetlesen establishes some important parallels between Spinoza and Buddhism:

As mentioned earlier, it appears that Spinoza’s chief remedy against the passions (cp. 5P4Sch quoted above) has a close affinity to Buddhist insight meditation (*vipassanā-bhāvanā*). Like insight meditation it starts with a certain

kind of mindfulness or awareness; it goes on to a particular kind of insight concerning the ontological status of external things, and culminates in that kind of adequate cognition, or wisdom, which alone can liberate a person in the absolute sense.

I believe the first of these points is brought out quite clearly in 5P3&Dem&Cor and 5P4:

5P3&Dem&Cor

An affect which is a passion ceases to be a passion as soon as we form a clear and distinct idea of it.

An affect which is a passion is a confused idea (3AffGenD). If, therefore, we form a clear and distinct idea of this affect, the idea will not be distinguished from this affect, except by reason, in so far as the affect is referred to the mind alone (2P21&Sch), and therefore (3P3) the affect will cease to be a passion.

The better we are aware of an affect (*quo nobis est notior*), the more it is within our power, and the less the mind suffers from it.

5P4

There is no affection of the body of which we cannot form some clear and distinct conception.

The second point I think is brought out in 5P2, which I quoted at the beginning of this section [ibid., p. 198].

If a person clearly and distinctly sees that his perceptions of things and egos in his life world are projections of his own imagination, he will develop what the Buddhists call insight, namely insight into the impermanence of things (*anicca*) and the unsubstantiality of egos (*anattā*). Thereby he overcomes the ignorance (*avijjā*) which was a necessary condition for his bondage under the passions (*dukkha*), and attains freedom instead.

(Ibid., pp. 198–99)

So far as I can see, Spinoza *can* plausibly be interpreted as Wetlesen suggests. It is an important, worthwhile interpretation. It makes it possible to accommodate central parts of Buddhist theory and practice within a philosophical framework keenly studied in the West (cf. ibid., p. 200).

In fairness to Buddhist traditions we must keep in mind that they contain a rich variety of conceptions, and that we are here dealing with only one.

What I am now going to say is not an argument against Wetlesen's interpretation, but an alternative.

The work required to get "a clear and distinct idea of a passion" may be, and has been, conceived as an analysis of the kind worked out by Freud

and later “depth” psychologists. At least so much is established, that for a person to get a deep insight into an affective-cognitive complex acquired in infancy is extremely difficult and takes a long time. The trust in substantial egos and permanent things is acquired in infancy. The Buddhist theory of nonsubstantiality (as interpreted by Wetlesen) undermines or destroys conceptual frameworks acquired in infancy. So, it seems very strange, from the point of view of psychology, that any kind of *instantaneous* clearness could be brought about. More likely, there may be a gradual and partial elucidation of passions. This does not preclude that a high degree of clearness may all of a sudden break through the barriers to invade consciousness. We know of such happenings from the study of religious conversion. (Deception is, however, more frequent than genuine sudden change of personality.)

What insight meditation might bring about is a sudden, fundamental change of *the general conscious, abstract conception of the world and the ego*. The particular cognitive-conative complexes are largely left as they are, but they are somehow seen at a distance even in the personal interactions of the sage with his disciples and the community. Spinoza *may* be interpreted in harmony with this—but it strikes me as unlikely that *any* change in the abstract *conception* of the world and the ego can permanently change the person. We have to observe behavior and attitudes during work in the community. The new conception may be an inspiration and a source of strong motivation, but it would normally take years, I think, to change the structure of the interaction between person and environment. Human beings cannot, however, gain deep conceptions independently of such structures. We show our most genuine conceptions in action. The rest is likely to be dishonest or superficial.

The levels of freedom in the sense of Spinoza have to do with a multiplicity of like relations. Whatever the intensity and depth of an instantaneous experience, one’s genuine conceptions change only gradually.

Absolute freedom is possible to the extent that one’s actions have *internal* causes and *internal* effects, according to Wetlesen. Interaction with the environment continues as before, however, or with even more pervasive external causes and effects if the sage gets a worldwide following. Spinoza’s idea of disconnecting passions from external objects does not entail a kind

of life within the self. The status of self is precarious anyhow, both for Spinoza and for Mahāyāna Buddhism.

Concluding Remarks

The many theses or hypotheses put forth by Wetlesen are supported explicitly through careful references to the works of Spinoza and others. A serious attempt to maintain opposite views ought to use the same excellent technique.

The foregoing has not consistently been such an attempt. It has the aim to make some of the hypotheses better known and to suggest alternative interpretations.

The supremely free human being according to Wetlesen's Spinoza is one of introvert tranquillity. The foregoing comments favor an activist interpretation: the free human being is a wise human being permanently and with increasing momentum on the road to still higher levels of freedom. The supremely free shows perfect equanimity, forceful, rich, and deep affects, and is active in a great varieties of ways, corresponding to the many "parts of the body," and all of them bound up with increasing understanding—and certainly including social and political acts.

Meditative tranquillity may be one of the free human being's methods for getting freer, but not a stable characteristic of his or her life.

This image of the sage has in common with (a certain variety of) Mahāyāna Buddhism the idea that the higher the level of freedom reached by an individual, the more difficult it becomes to increase the level without increasing that of all other beings, human and nonhuman. The obstacle to individualistic freedom is deep-seated solidarity. It again rests on identification with all beings. The individual self develops into the universal self. (In general "relationism," the term *self* can, and ought to, be avoided.)

The trend of reasoning pursued by Wetlesen leads also toward Mahāyāna Buddhism in the sense that the highest freedom cannot be a lonely freedom, or rather, it is not a freedom that can be reached going alone, and consummated alone. What I am objecting to is the conception of an absolute instantaneous freedom that is supposed to be *higher* than the freedom

SPINOZA

of the wise human being supremely active through a development reached not without painful labor and danger.

I wish to add to this conclusion that various methods of meditation developed within Mahāyāna Buddhism might be accounted for within the framework of a Spinozistic philosophy. Considering the growing appreciation of serious meditational practices in the West, the possibility of conceiving them within the broad and deep framework of such a philosophy must be greeted with joy.

Deep Ecology and Education: A Conversation with Arne Naess

Is deep ecology primarily about asking philosophically “deeper” questions, questions about one’s most fundamental beliefs, or is it about achieving ecocentrism or some other ecological goals?

Arne Naess: To ask deep questions is evidently not enough. As a supporter of the deep ecology movement, you have to go deep in your questioning, to what for you are the deepest beliefs. That is a necessary, but not a sufficient, condition of being a supporter of the deep ecology movement. What we see is that from the deepest premises some people derive the eight points, or key principles, of the movement. Others derive unecological consequences.

We have seen throughout the history of philosophy very deep questioning that, in my opinion, goes in the wrong direction. Thomas Hobbes, the great British philosopher, for example, did very deep questioning that led, from a deep ecology point of view, to very bad conclusions—consistent materialism and authoritarian political views. So there is no problem in the deep ecology movement about this. You have to ask a supporter to have some kind of life-lust, some kind of philosophical or religious premises. So that’s clear—go deep, but that’s not enough.

This interview was reprinted with permission from the *Canadian Journal of Environmental Education* 5 (2000): 48–62. Conducted by Bob Jickling, editor of the *Canadian Journal of Environmental Education*, it is based on conversations with Professor Naess held in Oslo May 29–30, 1998, and February 23, 2000.

If our task as philosophers and/or educators is to help people develop an environmental philosophy of their own, then must we accept the risk that they might come to conclusions we may regard as unsound?

AN: Sure. We may say, All right, these are your basic premises, these are your highest priorities, and from these you draw such and such consequences, but I'm afraid some of these consequences are not good, and I strongly object.

In spite of the disagreement, there are two different ways of going on with the dialogue. One is to question whether we have really derived consequences we ought to derive from our premises. The other is to see what can be modified: "Could you modify the formulation of your basic views?" Then you make a suggestion about the basic premise: "Could you agree to formulate the premise a little differently?" Then you try to be helpful in seeing different possibilities of interpretation of what he or she is saying. Before you simply say "We disagree fundamentally" or "We disagree about the consequences," go on with the dialogue.

So your emphasis as a teacher would then be in helping the students examine their premises and subsequent consequences—helping the students to clarify their thinking at each level?

AN: Exactly. That's right, to help these students articulate how they feel. There is a kind of endless process going on within our societies and between different societies. We may conclude after many discussions that there are some real differences of opinion among us. Then you have to find some basis for peaceful coexistence. We are not going to use any violence, in communication or otherwise, but we simply disagree. And then we can add, "If we didn't disagree on anything of importance it would mean that we were getting into a kind of completely homogeneous culture, which is a terrible thing, so better really to dislike each other's position than to have no differences."

Where policies are violently unecological, invite relaxed debate on a large scale.

Perhaps the continuing evolution of environmental philosophy provides a reason to give preeminence to the deep questioning process, and to be very careful about not imposing particular formulations?

AN: Yes. I look at myself as a kind of stream—not as an ego—and the stream goes on. That doesn't mean that I am a relativist. I am a relationist. You should have a self-respect and self-confidence that you can change and admit changes. There are many people who don't have enough self-respect and self-confidence. They are a little afraid of contradicting themselves, or they identify too much with particular positions, or they feel threatened.

As a teacher I'm aware of this: I think some of my students may not have a high degree of self-respect—be careful, take plenty of time to discover their background.

I'm interested in how you see relationships between deep ecology and other formulations such as social ecology, ecofeminism, . . .

AN: We tend to specialize. With this specialization there is a tendency to feel opposites instead of feeling the complexity of the relations and complementarity. I think that the deep ecology approach includes what we think is important in the social ecology movements, and also important things in ecofeminism. We are so grateful to work with these ideas. Deep ecology supporters must acknowledge that we sometimes have a one-sided view. We sometimes underrate participation in political debate, or we are unable to have meaningful discussions with economists.

I think some students force us, through their questions, to go deeper in our own questioning.

AN: Oh yes, and there you get to questions for which there is no difference between the competence of a professor and a youngster. If you go deep enough into life philosophy, you will reach a level at which people get together, whether they are professors or schoolchildren, at the same level.

I have a lot of conviction for what I believe and I go for it; I am sure that I will not change my opinion. At the same time, though, I see the possibility of changing to the opposite opinion. I have complete confidence in myself, yet I see the possibility that the next day, after some terrible experience, I may have a different position.

Your emphasis on the deep questioning process seems to be informed by an optimistic view of human nature. How would you suggest that we deal with the barriers that fear and prejudice represent? Is deep questioning sufficient?

AN: No, discuss the consequences. With deep prejudices you must use some examples of how you would behave in a particular situation. For example, in 1935 I was climbing a little with a strong supporter of Hitler. I had some pieces of bread and I said, "This was made by a Jewish girl. See if you can eat it anyhow." Then he admitted, "Well, I do not mean that absolutely every Jewish person is a terrible so-and-so. There are exceptions." With reluctance he would then eat just a little of the bread.

You have to, if you can, get into some practical situation—you start a walk somewhere, do something together, and then—bang—you have an example: "How do you look at this?" Then you may make this person change the formulation of what he or she has seen as an absolute truth. The Hitler enthusiast could be made less dangerous, less badly informed.

That's what they were so good at, the logical empiricists in Vienna. They were very different personalities, but sometimes one would say, "Could I formulate your view a little differently?" and another would say, "No, no!" "But could we formulate it this way?" "No." "Well, how about this way?" "Yes." You see, they invited one another to propose different formulations. It means that basically they were trying to help one another; there was a kind of research attitude. Instead of calling their philosophy logical empiricism, they should have had the slogan "Research attitude." They had four theses in philosophy that I thought were not valuable, but they had the searching minds required of insightful philosophy. They had an eminent research attitude. People did not understand this and often believed that which agreed with their own philosophy.

The cynical person might say, "Well, that example didn't do very much to stop the Holocaust," but the optimist might say, "Well, there weren't enough people 'sharing their bread'" as you described in your example.

AN: It was necessary not to hide what was going on, and our duty was to talk to people who were on the wrong side. I was in Austria in 1934 and 1935. What I found was that many were just following a trend—joining the bandwagon—and expecting nothing like what ultimately happened, holocausts. When people saw that things were going very wrong, they didn't stand up as much as they should have. I said, "If some are bad then you need not talk to them, but if they are very, very bad, then you may invite them to dinner." That is Gandhian. You must not leave them.

You've written about seeking ways to live both joyously in the world and according to obligations [see, e.g., Naess 1989].

AN: Some people think that I don't have an ethic because I don't have ethics of duty, but I say that ethics of duty may ultimately be based on the ethics of fondness, empathy, and what I call some kind of positive identification with something else. If you have that, you then formulate duties, saying, Whatever the situation, this must be done in this way rather than that way. So you understand that there are some things that are duties, such as you obviously have toward children. If you take the dramatic chance of being a father or mother, then there are a lot of things that you should formulate as duties, not only what you ought to do, but what you must do.

In environmental ethics I say, Never moralize. Sweep before your own door. In a rich country like ours we do things every day that we should not do, things that are not done in a consistently ecologically sustainable way. We are all sinners. Some people are very good at certain things, others are very good at other things, and scarcely anybody is very bad in every way environmentally. You have options. I might say, "I can't be like that, you are superior there, I'm going to have this bad habit." And Gaia says, "The earth is fantastically rich; you can have some of your bad habits—but here are the limits."

Environmental education has been criticized. Some claim the problem lies in programs and curriculum materials that are not objective and not grounded in facts. You have said: "Is not the value-laden, spontaneous, and emotional realm of experience as genuine a source of knowledge of reality as mathematical physics?" (Naess 1989: 32).

AN: I think this sentence may easily be misunderstood. What I intend to say is that in spontaneous experiences, experiences that you are confronted with every moment, you have as near a relation to reality as you can have in mathematical physics.

For example, when my Chinese wife was confronted with a Norwegian waterfall, she spontaneously saw it as a tremendous water channel that had leaked—an accident—and found it rather threatening. What she spontaneously experienced is exactly at the same level of reality as my experience of beauty and greatness. Mathematical physics, or any kind of science, cannot falsify the contact of the spontaneous with the real.

This is easy to comprehend in music. You listen to the opening of Beethoven's Fifth Symphony: *da da da dab*. That makes one gestalt, one whole. Then after *da da da dab* you get *da da da dab* an octave lower, and that's another whole—one of the smallest units that you have in a symphony. And those two together—*da da da dab, da da da dab*—make a more comprehensive gestalt. However, there is always a more comprehensive gestalt, more comprehensive wholes. For example, your experience depends upon with whom you sit. If you are in love with the person sitting with you, that will change the whole symphony—really change it.

If you suddenly hear *da da da dab* on the radio, your experience has to do with the whole symphony and not with just this part. You simply cannot think of existence, as a human being, without acknowledging that kind of experience. There is nothing in science that can undermine these experiences—saying it's wrong, it's mistaken, it's subjective.

Daily life has the character of gestalts rather than separate facts. Whatever we do, we are in a unitary situation that is extremely complex, but we are never in a merely factually describable situation. It's always a value situation somehow. For example, a parking lot is seen as tremendously well made technically, but there is a question of whether we should have it. We may experience a parking lot within a whole, an emotional gestalt, as a negative on a deeper level, which leads you to say, "I feel the policy is wrong." Such a feeling is a valuable starting point. Try to articulate what you feel!

Sometimes critics dismiss elements of environmental thought, and environmental education, as subjective evaluations, sentiments.

AN: There is an underestimation of the cognitive value of feelings. What people say in favor of economic growth is sometimes highly emotional. I can't see why I should be opposed to their personal engagement in this case. We do not like to rob our antagonist of feelings. It would be terrible if I met some opponent without any feelings. We may have, for example, a great feeling about economic growth. We all have feelings for this or for that. To say that how we relate to nature is a question of feeling—that's not interesting because it's so obvious, that we are subjects. How we relate to our children and how we relate to criminality are also questions of feeling. Really, there is no valid argument against the strong feelings for—or against—nature, but we may properly ask, Why do we have those feelings?

How, then, does a teacher tell a principal or school council responsible for her school that she wants to take kids out and have them get spontaneous experience, to nurture their gestalts?

AN: Some people have hundreds of good, joyful experiences that cost nothing. In the schoolyard itself, you find a corner where there is just one little flower. You bend down — you use your body language — and you say, “Look here.” And some answer, “There is nothing there.” Then you talk a little about what you see, “This flower here, it’s not the season for it. How can it be there this late in the year? And look at it. It certainly needs a little water; it’s bending, look at the way it bends. What do you see when it’s bending like this?” I call teachers who behave like this nature gurus. It is a little more like an Eastern kind of education, more in terms of personal relations. Try to make them see things they haven’t seen before. Use your body language. Even inside the schoolyards, you find nature’s greatness.

I remember in Tokyo, our car stopped unexpectedly. I found right there no building, but a small area of “weeds,” excitingly different from those in Norway. Consequently, I had a splendid time for a whole hour inspecting the strange weeds. Conclusion: teach children to value spontaneous crazy experiences—crazy because usually one would say, “There is nothing there.”

What advice would you have for those living in urban areas? Can we connect properly with deep ecological thought in only relatively undisturbed settings?

AN: We can do it in cities. You can do it along railways, highways. Everywhere there is something that is essentially nature. You don’t see any human purpose in it. It’s there on its own—and it’s ugly or it’s beautiful—but it’s there and its complexity is unlimited. To see something where you do not need to take any stand toward a purpose, or utility, or even beauty is a good thing. Even if you go to look at an art exhibit you are constrained, you are expected to like something and dislike something else. Whereas if you look at the sky—there are a fantastically lot of different clouds in Norway—you are free, and therefore free to straighten the imagination. More and more, I look at clouds. I did it as a boy, and now at the age of eighty-eight I am getting back to clouds—changing, changing, changing. There must be much more of that in school—keeping imaginations intact.

What I say here has to do with high-level environmental education.

There is a school in which they have wonderful semesters on the environment, but they say, We must start with chemistry; we have to have the facts first! People go to those places for a whole year of environmental immersion—they are not at all motivated by chemistry. Go straight into what they are motivated about; then later you can say, Well, here we have to do a little chemistry—use the term CO_2 and so on—but as part of a whole in which you always have the basic motivation of the students in mind. When there is care for the environment all the time, then put in some physics and chemistry. If they are not very fond of physics, chemistry, and statistics, let it drip in—into something marvelous.

You say that gestalts are complex and sensitive to introspection, that application of scientific observation habits will lower gestalt abilities—reduce people's ability to see wholes—if counterforces are not introduced at an early school-age level (Naess 1989).

AN: You learn as a child that there is something called knowledge, and soon children learn about scientific knowledge as something opposed to myths and the undue influence of feelings and values. You can easily begin to overestimate the importance of scientific knowledge in a vital question, which is always also a value question. As for ecology, we have had for a long time more than enough ecological knowledge about how to mend our ways, so in some senses it is a blind alley to ask for more knowledge; wisdom is what we need. Climate research, for example, will always be hypothetical in character, but we have to say, If there is an effect, then what are the consequences? Then people sometimes think, But it is not scientifically proved. We can't verify or falsify, in a strict sense, any scientific thesis. We must be quite honest that it is always hypothetical. A theory is born, has a life, shorter or longer, and a death. So you see, we have to undermine the prestige of scientific knowledge in favor of research, and of value priority.

Can you speak about the relationship between research and the valuations that underlie scientific knowledge?

AN: You can prefer, for example, a certain kind of methodology. You value it. However, you cannot derive the value of that methodology scientifically. You can only point to examples of how it has worked in particular cases—descriptive examples. Not all questions in research are on the same level, on

this descriptive level. You make choices that are normative, and those choices cannot logically be derived from descriptions.

I'm interested in the relationship between natural history and praxis as you see it?

AN: Instead of immediately introducing the term *ecology*, you may introduce relations of human beings to nature with the historical background—not the history of humanity but history in general. You can start holistically—integrate—in a mild sense of holistically. We can ask the philosophical questions “Who am I? Where am I? What do I want?” You can talk about human relation to what is not human.

Then I wish that we would let teachers say, “How do you feel the world? How do you feel yourself?” The term *feel*. “What does this feel like?” instead of “What is this?” We immediately get feelings into the teaching. We don’t have a life of pure cognition and a life of feelings as something separate. We start with both at once, and natural history is a good place to do that. So the extensive use of *How do you feel? What do you feel?* Then you inevitably get “What should you feel?” then “What do you think you are right to feel?” and “What do you want yourself to feel?” The praxis, human practice today in the rich countries, is detestable, and many want to feel it more strongly so that they are motivated more strongly.

The developmental years, those early years of school (and before), seem crucial. This brings with it a great burden of responsibility for those who care for and teach young children.

AN: I usually say that at four years old it seems to be quite natural to have a total view, a rudimentary philosophy of life. A total view would be the kind of view that encompasses him- or herself and the world. If you could talk with a four-year-old for a long time, you could probably describe an outline of the total view of this boy or girl, a view that is still uninfluenced by schooling. We should try to investigate more what happens between four years old and ten years old. We talk about socialization—after four-years it starts—bang! “This is how it really is, not how you fancy it is. This is how things are done. This is how we should feel. This is how you should think.” Five-, six-, seven-, and eight-year-olds are coerced to listen. Unfortunately, it is more and more believed that the earlier you start schooling the better.

So we have a very important function to find those who are writing good things about this time between ages four and eight.

But the reality is that we have a system in which we do put children in schools right away. And we have people responsible for nurturing their development — people who teach kindergarten and grades 1 and 2.

AN: I would then introduce the difference between science and research. If you let the four-year-olds continue the development in cognition, they will be researchers rather than scientists, they will be researchers and seekers, and they will be marveling just as much at what we don't know as what we do know. Lots can be done in upgrading the term *research* in relation to science. A good researcher may never pretend to have contributed to scientific knowledge. Teachers as researchers, or seekers, talk as much about what we don't know as about what we do know.

So, in the kindergarten you should have very few finished products of any kind, but many tools and very many natural things that the children can use. You should have projects that only faintly suggest what can be done.

There should be easy access to what I call patches of free nature. Those may be very small — not wilderness. Patches are where things grow without any design whatsoever, and if the body language of the teacher expresses concentrated attention, they all tread very lightly, very carefully.

One square meter of a meadow is so fantastically rich that there should be enough to discover for the rest of our lives. So you could have the children follow the small patch of free nature through several months: the same little flower, but now withering. Take just as much care of the withering plant as of the blooming plant.

Kit-Fai Naess: How could you expect five-year-olds to withstand social pressure, group pressure from not having this particular toy, from not having a Spice Girls CD?

AN: Yes, it's not a question of not having new things, but rather a question of keeping and valuing things. Show children, don't just place gifts in their hands. My small daughter already knew about radio when she came into the mountains. "Where is the radio?" she would say. Then, the next time we had a radio with us: "And here is your radio." Of course, for a couple of

days she used the radio, but after a week she never used the radio. The mountains did not encourage radio.

You have often said that you're an optimist for the twenty-second century. But what about a fourteen-year-old who is despairing, who's facing her whole life? If she thinks the world is burning up because of greenhouse gases, why should she care?

AN: There are some doomsday prophets, but there are no doomsday prophets among the serious ecologists. Not a single one. Every fourteen-year-old who cares should be told this. Ecologists tend to say that if we continue developing exactly as we do now, looking at statistics, we may then reach within a hundred years a catastrophe of a major kind such as major worry about access to clean water. There are often qualifying if's.

Serious ecologists also tend to say, If you would like to be with us, you are welcome. There are so many different kinds of things going on where you can help. So you can find your place. The twenty-second century may see the end of the ecological crisis.

I use the slogan "The frontier is long." There is a tendency to say, What I am doing for the environment is of the most important kind. Then the other one says, I am doing so and so; I think what I'm doing is of the most important kind. We never should say such things, because there are so many different tasks to be done and there are callings for so many different kinds of persons and capacities. If somebody is not yet an activist, we should find a suitable area for that particular person. Then say, Oh, excellent, we need people there. Just go on! We should not say, There are more important problems, you should do something else.

What about cynical students? Deep ecology perspectives are appealing to many environmentalists and educators, and yet we live within the cultural and economic systems that give rise to so many problems. We cannot isolate ourselves from these systems. For example, I am now in Oslo and you were recently in Victoria and Vancouver, yet the consumption of the vast quantities of fossil fuels required for such travel seems at odds with our values. Given these potential inconsistencies, it is easy to "tear ourselves apart from within" or retreat into cynicism or lack of interest.

AN: Well, I'd say to those who would like to be consistent, It's a high ideal to be consistent, and you will achieve it when you die—not before. As long

as you are an honest human being, you will see that you are inconsistent in ecological matters. And Gaia, she says to you, You may have a lot of bad habits but there are limits. If you have a bad habit, if you always must have the newest kind of camera—you can't also have the latest kind of tent. When I was invited to travel to the Antarctic, I could not resist the temptation, but I immediately announced that I would be glad to give lectures in Uruguay on deep ecology and the relationship between deep ecology and social ecology. So I said to Gaia, I am now going to Uruguay on your business, and then I might do this very bad thing: fly all the way from there to Antarctica. We are sinning in a sense, but we have a budget. You may think each year Gaia will give you a gift, a Gaia gift, of some ecologically bad habits—and the goal will be to have a little left even for Christmas. I never have.

If you live in Norway, it is very difficult to live all year within the scope of the gift, especially if you live in the city, so you must take into consideration where you live. You should think of this as a gift, and that She is very tolerant: She doesn't like it if you moralize to others—saying "I use the train, I'm not flying"—because we all are sinners in a sense. Very young people should be discouraged from trying to be perfect. Rather, they should try to classify bad habits and say, Here is a bad habit that really has some influence. Maybe I could change that—and then I keep some of the others.

Some people might say that this is an easy way to rationalize bad habit.

AN: It is an expression of realism, but of course it might be an invitation for some people to rationalize. On the other hand, there are people who feel and remember their imperfections too often, too much. Some are carrying a heavy burden all the time. So it goes both ways. Some need to be encouraged.

I once had a student who seemed to think it was an all-or-nothing game — who did not seem to see any incremental way to make a difference because we needed such fundamental changes in every dimension of our society. He seemed to throw up his hands.

AN: Well, here I learned from Gandhi. He had a vast revolutionary program, not so much to get the British out of India as to liberate the Indians from their own kind of authoritarianism and their corruption. He said, "One step is always enough for me. One step and then another one." We

have this one step as a major thing to accomplish—and having accomplished that little step, we then take the next step. “I am a compromiser, except on the fundamentals,” he said.

You may be a revolutionary in two senses, either try to make things happen fast and with violence, or make things happen more slowly and with nonviolence. Nonviolent revolutions are long-term revolutions. A revolution is thought to be something really important. It is about big things — like getting rid of slavery — but a minority, consisting of activists, is enough. The majority will hesitate, then say: “Well, I agree . . . okay.” A minority must stand up, as your students must do, stand up and say things. That’s an obligation.

Alfred North Whitehead once said that “the merely well informed man is the most useless bore on God’s earth” (Whitehead 1949: 13). At least partly to blame, he argues, is that they are overladen with inert ideas. And you have said, philosophical insight “should be directly relevant for action” (Naess 1989: 37). But is action properly an aim of education or a logical and practical consequence of having acquired an education?

AN: The education should itself consist of actions. You cannot have a dichotomy there. You can have something that is more like a piece of theoretical education and something that is more like a piece of creative action. When you walk—a little trip into nature with students—you cannot draw the line sharply at all between education and action, and you should not draw a sharp line between how you treat nature, how you behave, and how you act. We call this *friluftsliv* (Gelter, 2000). Life in nature is a major thing in Norway.

I stress the difference between activity and activeness. With activity you do things, play things. Activity can be seen by others, but in what I call activeness your whole person is active even though you may be completely quiet. No overt action. Moreover, something in your personality is somehow changing—maybe not always permanently, but for the moment. *Activeness* is an important term. You may point to somebody and think, He is in no activity at all; he has stayed at the same spot for an hour. Yet he may realize a high level of activeness.

In Japan a friend of mine helped me to gather about 100 people. We went into the forest at daybreak, and we said, Now let us say nothing to

each other. We will just listen to what the trees are saying. We had one hour of complete silence. We were active. We had a high level of activeness but showed no observable activity.

Many people are looking for mentors who work toward bringing their actions and their ideas together. Would you care to give an example from your own life about how you formulated a position and then engaged in direct action?

AN: For me, it was a question of whether we should get a lot of electricity by harnessing a great, beautiful waterfall. In this case the local population deeply liked that waterfall, and they were less interested in all the money from development—they preferred the waterfall as it was. I thought that was marvelous. You cannot join all the protests, but when there is something very special, you just leave what you are working at and you join in the protest, in my case at this waterfall.

If you wish to get into practical conflicts, you must train yourself. You must do the right thing but in a way that does not create antagonisms. For example, I always had excellent relations with the police, being arrested several times. I said, “I’m sorry I have to do this. I’m sorry, I have to lie down.” Then, as I was being dragged along, I once asked them, “Do you get told how to carry—so that you can carry many people without hurting your backs?”

You should have a lot of self-respect. You must believe you are entitled to civil disobedience, but only after genuine efforts to avoid it.

What about the teacher who lives on the west coast of Vancouver Island, who’s concerned about environmental issues and is living near a logging community? The teacher wants to explore issues concerning human–nature relationships and relate these to logging or fishing. When all is said and done, what is the role of action?

AN: If you find a particular environmental goal, then it is right for you to join in this direction, and invite the students to do the same while respecting the opponent fully. You only use, as I say again and again, the term *if*. If your priorities are in a particular direction, then it is appropriate to point toward relevant actions; but always act in a Gandhian way, always nonviolently. That implies maximum contact with the opponents and less talking with the converted. Let people in the logging community call you names, make it difficult for you. Never retaliate.

How do we nurture action without being guilty of leading students in the direction of our own ideologies?

AN: By means of the qualifying term *if*. You may say, “If we have a particular deep kind of priority and value, what then follows from this?” If you always use these qualifying if’s, then you are on the right side. You can go on arguing for three-quarters of an hour, but only if, from time to time, you preface a remark with the term *if*.

It is correct for you to lead people in your direction—toward what you think is right—but not in a wrong way. So it is completely right for you to do everything you can to have the community adopt your policy, but as a teacher, you should always do this with qualifying if’s: “If you have the following value priority, then. . . .”

I can’t help but think that we need to make space for something beyond advocating our positions, even with the if’s. In an academic setting, you can logically make your point with the qualifying if’s, but if you’re teaching school in a logging town, people threaten to remove their children from school if a teacher even mentions the environment. There is a great amount of fear.

AN: I understand. Better never mention “the environment” in class.

Let’s say we discussed an environmental issue for forty minutes. You may end up by clarifying the position of loggers. Clearly elaborate your own opinion, but don’t end up with that. End up admitting that the situation in your community is different from the situation in the community of your antagonists. We may continue to disagree, but let us look for areas of cooperation.

Arne Naess would be in pursuit of truth and validity. He would not claim an ultimate answer, but he would like to point in a direction.

How My Philosophy Seemed to Develop

Introduction: Motives for Psychoanalysis in 1934

Early in 1934, at age twenty-two, I found myself in Austria eager to climb mountains and study.¹ Psychoanalysis was at that time very close to the center of cultural attention in Vienna. It was therefore inevitable that I should ask myself, If I am to be an honest philosopher or scientist, would it not be prudent to go through a psychoanalysis? Was it not suspicious that in the first draft of my doctoral thesis I had introduced the notion of the “achievement” (*Leistung*) rather than the “meaning” of a sentence as a basic dynamic concept? Might it not have to do with my own, perhaps unwise, achievement-mindedness?

Soon I was in a deadly serious fourteen-month analysis, 8 to 9 A.M. every morning except Sundays, with the old collaborator of Freud, Edward Hitchmann. We were both somewhat astonished to find that I had suffered a pronounced childhood neurosis. It had obvious consequences for later life, and the analysis turned into a combined character analysis and analysis of my philosophical inclinations. Some of our findings may be of interest in tracing the genesis of philosophical inclinations in general.

First, I shall try to explain how I arrived at a set of rather basic attitudes and valuations. They will be suggested through a set of key terms. They are not philosophical in any academic sense, but given certain social and cultural conditions, they easily lend themselves to philosophical expressions.

This article was reprinted with permission from *Philosophers on Their Own Work*, volume 10, edited by André Mercier, Maja Svilar, and the International Federation of the Society of Philosophers (New York: Peter Lang Publishing Inc., 1983), 209–26.

Second, I shall try to show how these attitudes and valuations contributed motivationally to definite points of view in definite philosophical publications. The two parts of the argumentation are not clearly separated in the text that follows. I shall feel free to mix them when it is natural to do so.

Shorelines and Mountains: Infant Shoreline Naturalist

From the time I was about four years old until I reached puberty, I could stand or sit for hours, days, weeks, in shallow water on the coast, inspecting and marveling at the overwhelming diversity and richness of life in the sea. The tiny beautiful forms that “nobody” cared about, or was even able to see, were part of a seemingly infinite world, but nevertheless *my* world. Feeling apart in many human relations, I identified with “nature.”

If I disturbed a small sole it would swim around a little, but if no better hiding place presented itself, it would return to me and hide under my foot. We were friends and helped each other. I could make tiny crabs fight, but left alone they would avoid each other or, if forced to compete when eating, would threaten each other in a harmless and amusing way. I did not see much of the brutality that I later heard people attribute to nature. Later in life, it seemed to me more manifest among human beings.²

Tiny translucent shrimps would gather around me, staring at me and carefully inspecting my submerged surface. They liked to be fed. Their never-ending inquisitiveness, their gracefulness swimming backward was one of the hundreds of charming features of life as I experienced it. (It is strange to see that an eminent Chinese artist seems to have had the same kind of fascination with shrimps—and it is encouraging to see his painting of shrimps reproduced on postage stamps.)

Two things of clear relevance to philosophy in general and to my philosophy in particular are elucidated by the above: an enthusiasm for *diversity* and a lack of incentive to judge something (some life-forms) as unquestionably higher, nobler, more right, than any other. Key terms here are *equivalence*, *equivallidity*, and *egalitarianism*.

Life along the coastline fostered an inclination to inspect and contemplate the affairs of life from a great distance, but also to participate in a way. In a way, I say, because the social distances between human boys and shrimps are unquestionably large. Some key terms of a shore-life philoso-

phy are: *richness, diversity, multiplicity, equivalence, equivalidity, egalitarianism, peacefulness, cheerfulness*. These were qualities of life as experienced by a definite onlooker and participant. Obviously, if one takes shore life as a paradigm for life in general, including human life, such qualities will affect one's professional philosophy.

One condition, though, must be fulfilled: the experience of shore life must somehow be "traumatic," in a positive sense of "decisive"; it must somehow be associated with very deep feelings and drives. Here a neurosis may be decisive. I shall not try to go more deeply into the psychological background, but I maintain that the key terms suggest bridges of a combined emotional and cognitive kind, linking basic, very early, in part neurotic, experiences with specific philosophical views in my books and articles.

The feeling apart seemed to stem from a basic catastrophe in my earliest life. Because of the death of my father when I was only one year old, and the preoccupation of my mother with my two brothers who were in their early teens, I was left in the care of a maid. She was excessively kind and submitted to all my wishes. Thus, in summertime I would not tolerate being put into the bathtub except together with a fly. She had to fetch a specimen by climbing up on the windowsills. She was dismissed because of her excesses when I was three years old, and I was never able to love my mother properly as a substitute. It seems that I experienced the change as a loss of a whole world, and that I managed to procure a new one. Nevertheless, the desperation turned inward as a moderate but not insignificant urge to self-destruction and, according to Hitchmann, a masochistic bent. (I think that *destruction* is a better key term.)

The catastrophe remained psychoanalytically rather obscure in spite of intense work. We obtained analytical material in abundance from the age of five, but apparently I had by then already adapted to some extent to my new world.

The life-forms along the coastline obviously differed in cleverness. Some were completely helpless. It was easy to catch them and inspect them. Others were alert and complex in their reactions. I did not, however, attach more value to or have more respect for the clever ones. They obviously all had their own more or less appropriate lifestyles. Shrimps were impossible to catch with one hand—they were accustomed to attacks from one direction—but they did not understand the clever cooperation of two hands.

Their backward thrust sent them into my second hand, quietly placed behind them. I loved them in part *because* of their funny limitations, not in spite of them. Bigger fish were immensely clever and mostly saw me and disappeared before I saw them.

Distance and aloofness were only two of many ingredients in my seashore experiences. They were more pronounced as ingredients of mountain experiences.

Distance gives perspective and breadth of survey. To see a landscape, including human settlements, from the summit of a mountain inspires the contemplation of totality, but also a feeling of being above things, unruffled. To see the mountain from below fosters in some of us a longing for this unruffledness and equimindedness—and more so in a child with terrible things going on somewhere in the mind and body and bursting out in interminable nightmares.

From about the age of eight a definite mountain became for me a symbol of a benevolent, equiminded, strong “father,” or of an ideal human nature. These characteristics were there in spite of the obvious fact that the mountain, with its slippery stones, icy fog, and dangerous precipices, did not protect me or care for me in any trivial sense. It required me to show respect and take care. The mountain loved me but in a way similar to that of my two brothers, ten and twelve years older than I, who were eager to toughen me up.

Philosophically, such a cult of a mountain reduced the need for anything supernatural, anything protecting us directly or guaranteeing the meaningfulness of life. To the key terms *distance* and *aloofness*, we may add here *austerity* and *toughness*. Thus, my very early cult of a definite mountain from the age of eight enhanced rather than weakened the need and capacity for distance, perspective, toughness, and equimindedness.

William James introduced the terms *tender-minded* and *tough-minded* to characterize philosophers. I received a very strong push toward tough-mindedness from my elder brothers. Being tough, somewhat wild, and older than I, they found it their duty (they say) to make a real man out of their thin and timid little brother. (When sick children from hunger-stricken Vienna were sent to Norway in 1919 I was, to the embarrassment of my mother, taken to be one of them.) Their “training program” was tough. For example, they would put me in a snow cave and pretend to fall through

the roof, or they would throw me over small precipices into deep snow. What if I cried? Their version: they would tell me that if I stopped crying, they would stop their treatment. My version: serious distress on my part made them stop, one manifesting tenderness, the other a never-faltering, equiminded benevolence.

The “education” by my brothers left no doubt whatsoever that they loved me and that they could be trusted no matter what, but love got to be a rather tough affair. No nonsense, no sentimentality. This attitude seemed to come to the fore as a detestation and fear of being influenced by manifestations of spirituality and high-sounding notions. A *moral* reaction against Henri-Louis Bergson and metaphysics in general seems to stem from this.

Gandhi did not exclude bloodshed so long as the blood stemmed from the *satyāgrahi*. His spartan lifestyle and nonviolent militancy could be admired in spite of this background in spiritual metaphysics. Spinoza was clearly a tough nut even though he indulged in “romantic” notions like perfection and love of God. Thus, I could let my admiration for these two men of wisdom flourish without feeling guilt. My publications on Gandhi and Spinoza are colored by this admiration.

Two philosophical points were rubbed in through the naturalist experiences: egalitarianism and the value of diversity. A third, developed through the combined influence of these two, was a certain form of *scepticism*. Some points of view (like some animals) are clearly vulnerable from some other points of view (or some other animals), but why imagine that one definite point of view (one kind of living being) would not be vulnerable from *any* other? What value would there be in having something defeat all others? Philosophical geniuses are normally believed for a short time, but are then gently dethroned and left with the label “of considerable historical importance.”

Mephisto

I had a kind and cheerful cousin, one year older than I, my best and only real friend until puberty. Unhappily he was not in my neighborhood (Oslo) during crucial years of my boyhood and teens. He had a brother, ten years older than he, who was considered (at least by my mother) to be the black sheep of the family. He was a Mephisto figure full of sarcasm and cynical re-

marks about life, but he was remarkably kind and tender toward his little brother, who admired him and repeated his dark sayings—without understanding them very clearly, I suppose.

The (of course hypothetical) influence of Mephisto was rather direct: from him I understood that it was quite *possible* to utter the most infamous, sarcastic, and cynical things about parents, humanity in general, and grown-ups in particular. He also showed that it was possible to maintain that married life is absurd and most other venerable institutions abominable. Quite a discovery! In spite of his sacrilegious utterances, he was not struck by lightning. I felt that I had a basic freedom to make up my mind in any direction at all on any subject whatsoever.

Grown-ups reacted with a combination of horror, perplexity, and admiration when I found a little sarcasm appropriate, and I discovered what might be the sure foundation of the art of successful analytical philosophy: the concise counterargument or the old question “What do you mean?” My mother, extraordinarily talented in her choice of expressions, called me the light extinguisher. Because Mephisto was consistently kind and helpful toward my friend and me, I did not feel that destructive, or at least rather cynical, opinions were a symptom of *personal* hatred or aggressiveness. I regarded his attitude as an important one in fighting hypocrisy. Mephisto seemed really to hate its pervading influence. When asked why we did something, we tried to be courageous and mention only our least acceptable motives, hiding our best.

In my later discussions with logical empiricists I think that some of the high esteem they seemed to have for me as a young man derived from short, sharp, but benevolent, counterargument delivered at the right time without blushing.

The Immensity and Nearness of the History of Life

The Platonic saying that the unexamined life is not worthwhile is one that most, but scarcely all, philosophers accept. Personally, I emphatically endorse it. One of the early sources of this emphasis is clear.

H. G. Well’s *Outline of History* (1920) was the first widely read general history of life. Not only were civilizations far away from Europe in time and space treated earnestly and sympathetically, but also the prehistory of life

since Cambrian times, hundreds of millions of years ago. By chance I got hold of the book. What an immense and sudden expansion of my own life's frame of reference! I found that I ought to pay just as much attention to *all* this life history as to that of my own country. All geological periods had the right to be taken seriously and also all creatures, past or present. In my imagination I traversed the history of life again and again during long nights.

By the time I was fifteen the horrible nightmares, a characteristic consequence of my neurosis, had largely disappeared, but I still suffered from sleeplessness. Even today I find the twittering of small birds before day-break ambivalent. For many years they said to me, Sorry, another night with little or no sleep. Another day is near.

A crucial experience: I divided life history from the Cambrian onward into one week of nights—with my own life at the very end of the week. It would consist of only a fraction of a second. What would be worthwhile in this fraction of a second? I never doubted the correct answer: to have a look at the marvelous world, to find out a little about it. Human beings were the first species that had the capacity to become somewhat acquainted with the universe. Devoted scientists, or rather “researchers,” seemed to be those who could satisfy the yearning to find out about the universe, so I started feeling that research would be the right occupation in life. What a joy to get acquainted with the overwhelming richness of our planet!

From these experiences another variety of egalitarianism evolved: all creatures have their own “premises” from which they act. Brontosaurus had a very small brain but was not too stupid to survive many millions of years. *Homo sapiens*, with a lot of brain, *ought to* be able to live and do research just as long or longer.

The extreme shortness of individual life would make it important to limit myself to essentials in the sense of Ibsen's *Brand*, that is, to concentrate on research. No time should be lost to indifferent signs—*adiafora* in the terminology I later learned to know. Dr. Hitchmann found my resulting *Zeitgeist* extreme and deserving of close analysis. It was in his view rather unreasonable and also impossible to realize in a consistent way. (How did I justify thinking so much about the other sex? How about excessive mountain climbing?) Anyhow, emphasis on essentials easily led to emphasis on essence—the real nature of things and its real value.

PHILOSOPHICAL DEVELOPMENT, ENVIRONMENT, AND EDUCATION

The work of scientists devoted to the history of life I took to be a work of love and appreciation. Researchers seemed to be the only people able to maintain a consistently positive *basic* attitude even toward the ugliest and most terrifying creatures. Poets were seduced by beauty and form.

It took about forty years to undermine this prejudice formed when I was fourteen to eighteen years old.

From now on I hope I need dwell no further on purely biographical matters. Below I offer a chart suggesting some relations between certain kinds of attitudes and valuations of philosophic relevance.

Key Expressions		
diversity	equivalence	nonviolence
richness	equivalidity	populism
multiplicity	egalitarianism	antiauthoritarianism
naturalist attitude		optimism
distance	aloofness	
	equimindedness	
self-destructiveness	toughness	self-criticism
austerity	reductionism	fragmentation
	trivialism	

Naturalist Epistemology

Enthusiasm for science created in me a need to know what it might be. Could there be a *science* of science?

Just as I would learn about crabs by watching them, I would learn about science through observing the behavior of scientists. Much of their behavior is verbal, and I could not pretend not already to be superficially acquainted with their language and ways of life. But this “knowledge by acquaintance” (Russell) could not be turned automatically into a science of science. On a genuine metalevel, one is not permitted just to listen to scientists as close friends and use their conceptual framework uncritically.

I thought I found in the sophisticated “molar” and “purposive” behaviorism of E. C. Tolman a scientific basis for the understanding of both scientific *activity* and *knowledge*. This approach, and its detailed elaboration in my book *Erkenntnis und wissenschaftliches Verhalten* (Knowledge and scientific behavior, 1936), is no different from what is widely known today as

ethology. In principle it is no different from a kind of purely descriptive zoology of scientific knowledge.

Different sets of *Verhaltensweisen* (ways of behavior) include the sentence "The distance of the sun is 149 million kilometers from Earth" as an important ingredient. They correspond in part to different ways of measurement. The "content" of the piece of knowledge "expressed" through the sentence is neither the distance "itself" nor a more or less illusory phenomenon in our consciousness or our brain, but rather definable in terms of sets of kinds of behaviors. The point of view is related to the operationism of Bridgman, but at a deeper level in opposition to it.

Karl Popper and other logicians of science were astonished and nonplussed when they heard after the war that I still looked upon the scientific enterprise from the point of view of a naturalist. Not that I thought the ethological approach should be the only one. There might be indefinitely many other approaches with equal, or rather, not less, merit. After all, science is only a few thousand years old; science of science is scarcely a hundred; and we might have millions of years to go, if we survive the immediate future.

The genesis, as far as motivational history goes, of my behavioral research on rats and human beings is in part clear. Students at the Sorbonne in 1931 made me an enthusiastic reader of Henri Bergson. I tried to construct a conceptual framework for the understanding of science through "*les données immédiates de la conscience*," but I found that one never gets out of consciousness if one starts there. The whole introspective approach, including that of Husserl, seemed to me to be based on a grand illusion. Bergson and Husserl (in his Cartesian mood) were seducing us, I felt, through lofty visions. They disabled us as real down-to-earth researchers. Perhaps one could learn more from plain observation of learning in rats and rabbits. (The latter animal is referred to repeatedly in my work on scientific behavior.)

Consequently, I went in 1938 to Berkeley, where Tolman received me cordially and let me carry out extensive experiments on hundreds of young innocent rats. One problem: if rats were confronted with an increasing number of choices of where to perform a difficult jump, would their power of action diminish? That kind of problem had vexed me for seven years: my Marxist friends combined great power of political action with essentially

one-track minds, whereas I hesitated and went politically limp, perhaps because I saw and contemplated many, mutually nonconsistent possibilities.

It turned out that rats retained their jumping capacity but showed increasing hesitation and discomfort—measured by the number of defecations and urinations, poor friendly animals! Exactly what, though, could be inferred from that result? Very little, I ultimately concluded.

In angry reaction to the spirituality of Bergson and Husserl and to German introspective psychology of knowledge, I adopted a kind of “objective” epistemology, which helped (or misled) me through the attitudes and value judgments suggested by the above-mentioned key terms *toughness*, *reductionism*, *trivialism*, *austerity*. I was also assisted by the “naturalist attitude” toward scientists. In Berkeley 1938–39 I placed myself behind a rat psychologist who placed himself behind rats. I traced the movements of the psychologist’s head and hands while he traced the movements of the rats.

The key terms *distance* and *aloofness* also apply here, because an essential ingredient of the naturalist epistemology is to avoid relying on spontaneous acquaintance with the scientists’ concepts and explanations, instead approaching the terrestrial scientist as a kind of strange creature inhabiting a strange planet. The operationalist describes operations in terms used by the scientist himself when he describes them. That gives a caricature of metascience.

The key terms *scepticism* and *self-criticism* do not apply to the above-mentioned work directly, but to the public discussions that it started. In a reply to H. J. Pos, I said that the metascientific *model of scientific knowledge* is only one out of indefinitely many, and that just as the behavioral metascientist places himself behind the scientist, meta-meta-researchers representing different approaches may place themselves behind the behavioral metascientist. Perhaps even the key term *self-destructiveness* applies, because what I did was very nearly to say that I had not *asserted* anything whatsoever, just pointed to a scenario. I did not want to compete with anybody. Today I wish to retain something both of the book and of the extreme pluralism implied in my meta-meta-reflections about the book—but exactly what?

The naturalist approach is neglected in Western academic philosophy in favor of epistemic logic, logic of discovery, and other approaches that avoid broad empirical confrontations. It is as if logical considerations were regarded as more philosophical *in themselves* than empirical considerations.

The Richness of Amateur Philosophies

It is difficult to introduce a concept of truth in epistemologies whose intent is to overcome the absolute distinction between subject and object. This certainly holds good of behavioral approaches. So I was led to take up the broad debate on concepts and criteria of truth, but published only one monograph, *Truth as Conceived by Those Who Are Not Professional Philosophers* (1938). Among the nearly one hundred themes I identified in the debate on concepts of truth, I selected one kind that had never before been taken up seriously: exactly how *true* and related words are actually used in society, and how “ordinary” people conceive truth.

The motivation brings in the key term *self-destructiveness*: the chosen theme could not possibly lead to any contribution to the vast and deep problems of truth as conceived by professional philosophers. Furthermore, I knew that the extensive use of questionnaires and statistics was detested and scorned by “genuine” philosophers. My predecessor in the philosophy chair at the University of Oslo tried to persuade me about two things, to apply for the professorship and *not* to send in my *Truth* monograph. Otherwise, he could not vote for me. That clinched the matter: *I had to* send in that work. (I was nevertheless appointed in 1939 against his vote.)

The empirical study of ‘truth’ made me jubilant and happy; people who had never read philosophy and never thought about my questions answered spontaneously with an astonishing richness, diversity, and multiplicity of opinions. Practically all the main kinds of “professional” views were expressed—not in a sophisticated way, but at least as embryonic philosophies. For example, extremely terse and pointed formulations such as *that it is so* were produced as answers to “What is the general characteristic of anything that is true?” Verification conceptions of truth were expressed through formulations such as *that it is shown (to be the case)*. If quotations typical of Plato were offered, counterarguments in an Aristotelian vein were produced.

To my delight, some people down to the age of fourteen could be classed as Pyrrhonic or zetetic sceptics in the sense of Sextus (Ph, 1,1,1). They would say that no truth had ever been definitively established, but they did not think of this opinion as definitively established either.

The study of truth and a series of other, similar studies, mostly unfin-

ished and unpublished, supported me immensely in my attitudes and valuations (also) with the key terms *egalitarianism*, *populism*, *antiauthoritarianism*, *optimism*. They embarrassed colleagues in the humanities, however. At least one of them found it deplorable that Norway's only full professor of philosophy studied the philosophies of housewives instead of that of Plato. Sure enough, my studies gravely undermined my already shaky belief that there was anything that we professional academic philosophers could perform today better than amateurs and decent, empirically minded, interdisciplinary researchers.

What about the richness and equivalidity of *professional* philosophies? Provoked by mutual distrust between existentialists and the analytically minded, I published *Four Modern Philosophers* (1968a), taking care not to reveal any differences in my estimation of Carnap, Wittgenstein, Sartre, and Heidegger. Carnap complained mildly that I had compared him to a schoolboy.

Logical Empiricism and Empirical Semantics

Valuing mountaineering and life among mountains higher than university studies, I chose to live in Switzerland once I had received the degree of master of arts (1933). After comparing prices, however, I went to Austria instead. In Vienna I by chance dropped into the famous seminar led by Moritz Schlick and Friedrich Waismann. The logical empiricists received me with touching cordiality, and for some years treated me as a new comet on the philosophical firmament.

My main grievances were only two. First, in spite of their brilliant intellects, they seemed really to believe that they had found some truths. I looked upon their views *only* as fruitful research programs, consisting of rules of considerable, but limited value (Naess 1936a, 1938). Their working hypotheses could only be confirmed through interdisciplinary research, mainly empirical with only a dash of formal logic.

The second grievance was their belief that the study of language and formal logic could somehow contribute in an essential way to the "solution," or at least "dissolution," of philosophical problems. Instead of slogans such as "physicalism" they ought, I thought, to adopt that of "research behavior" (Naess 1936a). I mention these grievances because they have

much to do with understanding the main goal of my largest work, *Interpretation and Preciseness* (1953 [SWAN I]).

In that work it is implied that terms of daily life, and to a lesser degree also technical terms in wide use, permit of an indefinite variety of interpretations presupposed or postulated by philosophers artificially to narrow down the options. Underestimation of the range of interpretations reduces insight into the richness of tenable positions concerning problems of vital interest.

The turn of (Western) philosophy in this century toward language rather than cosmos, toward logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind alley.

Communication, and especially *preciseness* in communication, depends upon interpersonal synonymity relations. These are worthy of decent empirical research, but it costs great labor to carry through the investigation even of seemingly simple relations. Thus, the turn from cosmos to language is not a shortcut to truth.

Even a superficial inspection of *Interpretation and Preciseness* makes clear the emphasis on diversity, richness, multiplicity, and searching rather than finding. The same holds for my survey of concepts of democracy and ideology (Naess, Christopherson, and Kvalo 1956).

As the leader of the project on ideological controversies between East and West at UNESCO (1949–50), I had the chance to indulge in the multiplicity of interpretations of *democracy* and related terms. With the able assistance of the young political scientist Stein Rokkan, we were able to undermine the grave accusations in the Eastern European camp that the terms were *misused* in the West, as well as the indignant reproach in the West of evil misuse in the East. Not only were *diversity*, *richness*, and *multiplicity* key terms, but also *nonviolence*, *aloofness*, and *equimindedness*. We corresponded with about 450 scientists and politicians on hotly controversial problems. The resulting volume, edited by R. McKeon and S. Rokkan (1951), was promptly sold out and never reprinted by UNESCO owing to the politically dangerous character of its contents (see *ibid.*, pp. 447–512).

Diversity and Nonviolence

In several books and a great number of articles I have promoted the nonviolent solution to conflicts. I have supported the Gandhian active nonvio-

lence (*satyāgraha*) and tried to show philosophical principles from which it can be derived (Naess 1974b [SWAN V]). Gandhi contrasted “the law of the jungle” with ethical law as intuited by man. Placing human societies and myself, as I had, within the framework of an essentially homogeneous, all-embracing Nature, and admiring and feeling nearness to the small carnivores along the shore, how was it possible for me to come early under the strong influence of a Gandhian ethics of nonviolence? As mentioned above, the life to be found in shallow waters may be conceived as essentially peaceful, and favorable to a norm of maximum diversity, richness, and multiplicity. Since Darwin there have been undercurrents stressing the evolutionary importance of symbiosis—the capacity of living together with or without mutual benefit (Krapotkin and others).

A human being who has not been deeply hurt by suppression, hatred, or lack of support and care can *identify* with all living creatures. The sufficiently mature person experiences joy on seeing joyfulness in others, sorrow on seeing sorrow. The mature mind also sees the vast differences of conditions under which fellow creatures live, and understands that the differences will (and should) foster a vast variety of ideas, behaviors, lifestyles, and cultures. To contribute to the maximum richness of differences, human beings should counteract only the growth of ideas, behaviors, and lifestyles that threaten this very richness. We cannot remain passive in the face of such growth and the conditions for that growth.

Does not this imply firm beliefs and therefore a rejection of scepticism? As developed in my *Scepticism* (1968b [SWAN II]) I favor a *zeteticism*, a fundamental openness based on concepts and intuitions of equivalidity. When diversity goes deep enough, a kind of generalized *de principiis non est disputandum* has to be adopted. This implies rules of behavior that harmonize with those of nonviolence in conflict situations.

The self-destructiveness revealed in the psychoanalysis was sometimes clear to me in the 1960s when I was defending scepticism and elaborating my view in book form. I could myself object against my work: “Professional philosophers look upon a defense of scepticism as a defense of the ridiculous view that you don’t *know* that no elephants swim in your soup. People at large inevitably feel that you defend doubting and negativism. The way you write is therefore quite misleading and apt to eliminate you as

a serious participant in philosophical and social life. But perhaps this is what you secretly wish!”

Ecosophy

The global ecological movement touched off by Rachel Carson gave me an opportunity to gather together most of the themes of my philosophical works in systematic form under the heading *ecosophy* (a large number of these publications are now available in English in volume 10 of the SWAN series). It is a kind of total view inspired by, but not derived from, ecology. Its emphasis is on basic norms and hypotheses concerning the relation of man to an all-embracing reality. A model (and therefore a conscious, deliberate simplification) takes “Self-realization!” as a fundamental norm. The self to be realized is not the ego, but the large Self created when we identify with all living creatures and ultimately with the whole universe, or Nature in senses close to Spinoza’s *Deus sive Natura*.

It is often said that the discovery that the earth is not the center of the universe has made man smaller. It has diminished his status. I have always felt that I grew bigger and bigger with the extensions in time, space, and cultural diversity. The universe is *my* universe, not my ego’s but that of the great Self we have in common. This is metaphysics, but through philosophical research it can be developed in the direction of clarity and cognitive responsibility. From the fundamental norm “Self-realization!” plus hypotheses about the world, I derive a set of principles for “Green politics.” In this way, abstract problems of philosophy are connected with concrete issues of contemporary political conflict.

The elaboration of ecosophy and the participation in social conflicts in favor of Green politics furnish cultural expressions of nearly all my youthful dreams and reflections. I shall not repeat the key terms, but refer the reader to the survey listed earlier in this article.

Some of the terms need comment, however. Austerity contributes to the picture of a life rich in the realization of intrinsic values, but simple—even spartan—in the use of means. Toughness is required in the nonviolent fights, in protection of nature, soft technology, cultural diversity, and decent lifestyles. Self-destructiveness, reductionism, fragmentation, and triv-

ialism are, it is to be hoped, gradually eliminated—but what about self-criticism?

On the Way

There is nothing in “ecosophy,” or in any other, more fragmentary work, that I would regard as established. On the contrary, I feel that all I have published has been “on the way.” Before proofreading is done, I have normally fathered heaps of notes for improvements, modifications, and elaborations. When I leave a subject and proceed to something new, it is always because I am impelled to do so by the movement of my own thought and actions, not because what I leave seems well enough worked out and accomplished. With greater talents, I would have produced better-rounded-off works, but basically I think that human beings are something essentially on the way, destination unknown, and that they are justified in expressing themselves, talented or not, as they move along.

Series Editor's Introduction

Arne Naess — A Wandering Wonderer: Bringing the Search for Wisdom Back to Life

[The pre-Socratics'] attitude, in the main, was genuinely scientific whenever it did not merely embody the prejudices of their age. But it was not *only* scientific; it was imaginative and vigorous and filled with the delight of adventure. They were interested in everything—meteors and eclipses, fishes and whirlwinds, religion and morality; with a penetrating intellect they combined the zest of children.

From this point onwards, there are first certain seeds of decay, in spite of previously unmatched achievement, and then a gradual decadence. What is amiss, even in the best philosophy after Democritus, is an undue emphasis on man as compared with the universe.

Bertrand Russell, *History of Western Philosophy*

When the full scope of Arne Naess's philosophical contribution is examined carefully and placed in context, it will very likely be viewed as one of the twentieth century's most significant and enduring.¹ Naess has made bold and innovative contributions to conventional academic philosophy and social research, particularly in the areas of behaviorist epistemology, empirical semantics and communication theory, scepticism, scientific and cultural pluralism, Gandhi and Spinoza scholarship, normative systems theory (as a general approach for exploring premise-conclusion relations), and the very idea and relevance of total systems (total views in Naess's *lingua*). Perhaps even more significant—although one should not view it as distinct or decoupled—has been his commitment to reconnect philosophy to life experience. This effort is similar to Bertrand Russell's in that it has been particularly pronounced in later life. Naess, however, carries this com-

SERIES EDITOR'S INTRODUCTION

mitment to expand philosophy's sphere of concern to life in general and the Earth. Essential to this endeavor, is the mature Naess's radical initiative to reconceptualize reason expansively, to integrate reason with emotions and feelings *in practice*. In some cases this includes using mythopoetics to make a case or communicate a point.² What makes Naess so special is that even while paddling against the current, he exhibits tremendous optimism and openness, joy, and a disarming, infectious playfulness.

Naess strives to *live his philosophy*. For more than thirty years, he has sought to reshape the philosophical debate by drawing from and building on his previous work to outline a nondualistic, nonanthropocentric philosophy of life that affirms the ultimate unity and interdependence of all living beings, while maintaining their individuality. His philosophy celebrates the Earth's richness and diversity—both cultural and biological. That said, one of the main purposes of the *Selected Works of Arne Naess* (SWAN), however, is to provide you, the reader, with the resources to make your own informed judgment regarding the significance of Naess's philosophical legacy.

At age ninety-two, Arne Naess has lived a long life filled with wonder. In his words, he has “seen life”—traveling the world, spending significant periods of time on every continent. He has experienced the world somatically and intellectually in concert as one mind-body—as a being—and seen more than most of us can imagine.

When Naess was born, Archduke Francis Ferdinand was alive, automobiles were in their infancy, and most homes did not have running water. Home refrigerators had just begun to be produced. Television and computers were only imagined. Only a few years before, after being contemplated for millennia, the first controlled and sustained powered flight took place, ushering in a period of ever-accelerating transfer of materials and information, but not necessarily a commensurate increase in knowledge or wisdom.

Consider that Naess has lived through two world wars (and too many “limited” conflicts to count), the rise and fall of the Soviet Union and East Germany, the “liberation” of India and Pakistan, the onset of climate change, and the hastening of “global terrorism.” He has been the beneficiary of tremendous medical advances and unprecedented economic growth, and he has seen the ravages caused by escalating consumption, globalization, and disparities in both income distribution and access to resources. He is part and product of humanity's largest growth spurt. And he

SERIES EDITOR'S INTRODUCTION

has witnessed the most significant loss of cultural diversity and the onset of what may become the planet's greatest extinction crisis—but is surely the greatest extinction crisis ever caused by one of Earth's own species. Naess has also seen and, at times, participated in the many hopeful responses to these ills—the peace, social justice, and ecology movements; nonviolent actions to support antiglobalization efforts and protest dam building; voluntary simplicity; conservation biology; wildlands philanthropy; bio-regionalism; green business and architecture; ecological design, economics, engineering, and restoration; and sustainable agriculture, forestry, and fisheries management.

Everyone is influenced by the times and events of his or her day. The “prejudices of our age” filter into our lives and work more or less consciously and actively, but at a minimum they enter passively. What is the mature Naess's approach to philosophy, how is it a uniquely self-aware and responsive product of his day, and why should it be seen as monumental?

Naess likes to see himself as a “philosopher of life.” The thought of simply being an academic philosopher—living a life of the mind—makes him restless and uneasy. For Naess, “wonder” is both the point of departure for philosophy and the focus of the enterprise. He is the philosophical equivalent of a hunter-gatherer using his wits and intuition to seek out food (for thought) in a fecund landscape. As they were for the ancient Greeks, science and philosophy are inextricably intertwined for Naess. Science, as the application of reason through empirical investigation, cannot be separated from rational reflection on the nature of reason, and vice versa. For the mature Naess, though, philosophy and science are also distinct. Philosophy is the unique realm in which we take up the deepest, most profound, and most fundamental problems. From Naess's vantage, which defines philosophy openly and discursively, the questions that have fascinated and plagued people for millennia have not changed much and they are not likely to change significantly in the future.

Naess's view of philosophy includes the traditional epistemological question “What can we know?” and the ontological question “What main kinds of things are there?” But it also includes “How do we measure?” and “How do we know?” as well as “What is the relationship between the knower and the known?”³ These are questions that are likely to vary with cultural and social circumstances, but this does not, for Naess, imply cul-

SERIES EDITOR'S INTRODUCTION

tural relativism. By its nature, this view of philosophy runs counter to the dream of the logical empiricists; it cannot be restricted to investigations of “fact” or “logic.” It is imbued with fundamental valuations. Being a philosopher, for Naess, is thus a deeply personal and intimate matter that requires us to engage all of our powers and experience. It should also include questions such as “What are your aims in life?” and “What’s driving you?” as well as encourage a practice of deep and open argumentation by asking repeatedly, “Why do you hold that *p*?” in order to unearth underlying premises and hypotheses. For Naess, all these questions have an empirical component. He sees it as a duty for a philosopher to extend research into the creation and use of empirical methods to address these aspects, unless these questions can be adequately addressed by an existing empirical science, in which case it is fine for a philosopher to perform research here, but it no longer constitutes a *duty*.

In Naess’s view, philosophy is ultimately concerned with how *we*, through our experiences, perceive the world, the world’s relation to ourselves, and the basic features of the condition of people. It is the realm in which we pose sophisticated questions to address perennial problems, probe them from different angles (in Naess’s case, from as many angles as possible), and test and apply the insights to real life—to what we do and decide every day. Its purpose is not to arrive at definitive answers. The purpose of philosophy, rather, is to help us understand what *we* believe in from our innermost perspective, expand this perspective continually, and facilitate communication—so that we might contribute toward improving the state of affairs of the world.

While initially attracted to Bergson’s *les données immédiates de la conscience* (the immediate data of consciousness), Naess grew disenchanted when he recognized that one becomes lodged in an endless circular loop and never exits consciousness. Naess clearly believes that the unexamined life is not worth living (his life is a testament to Socrates’ edict), but he appreciates that disembodied, introspective examination comes at great peril. A mind-centered focus on “examination”—where subjects exist separately from objects, theory is isolated from praxis, and knowledge is decoupled from wisdom—very quickly degenerates into meaninglessness. Worse yet, separating people from and raising people above nature and the coevolutionary process that created us—and provides for our sustenance—can be inimical to life and the evolutionary process.

Nature, that which is, the reality of the pre-Socratics, is Naess's philosophical palette, not the "world" of his own consciousness as has become the norm with so many contemporary philosophers since Descartes. Popper and others posit the existence of three worlds that correspond to the development of our commonsense view of reality. World I is the physical world, the "external world," the world of our sensory impressions. World II is the world of all conscious experience, the psychological world of the "immediately given," which incorporates our feelings and intentions. World III emphasizes the logical content of reality. Naess finds these multiple views of reality unconvincing and potentially dangerous. With a worldview inspired by Spinoza's *Ethics*, he is fundamentally opposed to the notion of multiple worlds.

Naess's mature philosophical approach and contributions are shaped by full engagement with a relational reality, in which no firm subject/object, substance/property, universal/particular, fact/value dualities exist. John Muir's famous, deceptively simple aphorism sets the stage: "When we try to pick out anything by itself, we find it hitched to everything else in the universe." Reality as we experience it, according to Naess, is a dynamic, multilayered manifold of hierarchically related gestalts—of which we are always a part. It is the opposite of atomism. Contrary to the dominant, Western way of viewing reality, there are no extrinsically connected discrete objects or "things in themselves" in the sense of Kant's *Ding an sich*. With Naess's "gestalt ontology," there is no dualistic "I" standing outside of reality looking in. Living beings, individuals in the sense of Spinoza's modes, are spatiotemporal manifestations of "one substance," nature or reality. As Naess points out in *Freedom, Emotion, and Self-Subsistence* (SWAN VI), Spinoza's medieval terminology of substance, mode, attribute, God, and Nature is dispensable. In addition, Naess goes on to characterize "living beings" broadly to include individual organisms as well as ecosystems, rivers, mountains, and possibly Earth (Gaia).

Naess's view of reality calls for a gestalt shift. His gestalt ontology does not stop with gestalt psychology's simple notion of holism, where the whole is more than the sum of the parts. It goes on to add that the internally related subordinate gestalts are themselves more than mere parts. There are no parts as parts or wholes as wholes; higher-order wholes are not reducible to lower-order wholes. The concrete contents of reality have gestalt character. For Naess, we experience reality spontaneously and our

SERIES EDITOR'S INTRODUCTION

experience of the world is made up of gestalts. “[This] is the world we experience. Nothing is more real.”⁴ People create abstract structures to reflect on or analyze spontaneous experiences and their structure; they are the interrelations between spontaneous experiences. Mind and body are mental contrivances and conveniences—abstract structures in Naess’s parlance—for helping us to describe, model, or understand certain states of affairs. They are not the contents of reality. Only individual occurrences of spontaneous experience make up the concrete contents of reality.

What are the consequences of Naess’s “ontological realism” as expressed in the form of gestalt ontology? First, living organisms have different levels of access to reality, based on their capacities, experiences, and backgrounds. This implication of “reality is one” plays a central role in the mature Naess’s approach to philosophy of science. One of his main thrusts is to undermine the claim that the exact physical sciences show all that is, that they have a privileged view of reality. In his view, science creates extremely abstract structures of what is real, but those structures do not actually *describe* any of reality’s concrete contents (descriptions are themselves normative). Jakob von Uexküll, the famous ethologist of the early twentieth century, whom Naess read closely in his youth, helps clarify this notion. “As the spider spins its threads, every subject spins his relations to certain characteristics of the things around him, and weaves them into a firm web which carries his existence.”⁵

Different people experience reality differently, yet we often, incorrectly, speak of *different realities* as if they existed. By the same token, identical accounts of reality in no way imply verification of that view by correspondence; from Naess’s perspective, such accounts by themselves are merely a sign of cultural poverty. “God” could have created the Earth and life 6,000 years ago, but the evidence to support this case is thin and the evidence to support evolution is stronger, in part because biological science and paleontology generally employ a greater level of depth of intention and thus aspire to maintain higher standards for the evaluation of evidence. Radical pluralism and scientific possibilism do not imply scientific or ethical relativism.

There are at least four other key implications of Naess’s gestalt ontology. First, the existence of one, interdependent reality tends to curb solipsism. Second, the world we live in spontaneously can no longer be characterized as merely subjective. Expressions such as “the social construction of

nature" become oxymoronic. Third, individual organisms exist as knots in a biospherical web or net. Reality is not anthropocentric; it is not particular to humans. Fourth, humanity can no longer justifiably be seen in opposition to a separate object—nature. This insight tends to temper any "natural" tendencies toward anthropocentrism. As with Leopold's Land Ethic, people become plain members and citizens of the biotic community, albeit ones with unique powers and proclivities and thus special responsibilities. We are all individual beings, yet we vary in the extent to which we are integrated into the whole.

Humans are massively altering the gestalt character of reality, diminishing it, making it less complex. We do this, Naess argues, without necessarily recognizing we are doing it or the extent to which we are doing it. Thus, we are unable to evaluate the tradeoffs of making such decisions. Naess argues that we generally act simply according to how we "see" reality, but there are aspects of reality that may not be available to us. These aspects are no less there because they are currently unavailable to us, yet they can be destroyed very easily. Sometimes we also confuse our abstract structures of reality (models, data, concepts, etc.) with the contents of reality and vastly underestimate the complexity of internal relations between gestalts, leading ourselves to believe, incorrectly, that higher-order wholes can be reduced to lower-order wholes. It is Naess's hope that by embracing gestalt ontology, we are encouraged to cultivate our opportunities and faculties for experiencing reality more fully—for experiencing more complex, higher-order gestalts. It is also his hope that we will openly and more carefully consider, in advance, how a proposed research program, action, or decision might affect other peoples' (or other life-forms') opportunities for rich spontaneous experiences (consider, for example, the possible impacts of ostensibly beneficial research on nuclear fission or molecular biology). In the end, however, we should remember Naess's own caution—his description of gestalt ontology is itself an abstract structure. As Naess says, "For me reality has always been something slippery to handle. I seem to grasp it firmly, but like an eel, or even a small lively trout in shallow water, firmness of grasp does not guarantee against escape."⁶ But does reality really have gestalt character?

Truth—as in *the* truth—is not a defensible notion for Naess. For too many academic philosophers, wonder has been extinguished and replaced

SERIES EDITOR'S INTRODUCTION

by a belief that definitive answers have been found, that the original, initially vexing questions can be laid to rest. Naess is under no such illusion. He views humans as essentially fallible and he sees this domain of fallibility as extending to mathematics and formal logic. This may be why he so freely returns to previously explored material (sometimes just after writing it) and looks at it afresh, with new and frequently competing and even conflicting insights. For Naess, truth is something we seek continually without expecting or believing that it can be found. He seeks peace of mind (*ataraxia*) by suspending judgment (*epoché*). While necessity requires him to take firm positions in life, he often resists taking such positions in his written philosophy. Having reached a general state of mental suspense (*isothenia*), he prefers, as a mature sceptic, anticipating his own tendency to come up with counterarguments and counter-counterarguments, to suggest alternative paths, inspire new ways of looking at things, and foster informed, open-minded debate. This *zetetic* inclination, although nascent in many of his earlier works, was made explicit and became a central theme in his philosophical writings in the 1960s.

For Naess, passivity has no place in philosophy or life. In his famous debate with Sir Alfred Ayer, Naess defines Spinoza's *amor intellectualis* as a "kind of loving attitude towards what you have insight into, while considering it in an extremely wide perspective."⁷ For the mature Naess, *amor intellectualis* involves using his technical and intellectual training to articulate, in direct and forceful ways, his attitudes and evaluations on matters of practical consequence. Like Spinoza and Gandhi, Naess is concerned with human salvation in this world, but Naess, with his concept of "wide-identification," expands this concern to both humankind's relationship to life in general and the self-realization of all life-forms for their own sake. Whether it be understanding how lay people conceptualize truth or experts characterize democracy; considering how our approach to science not only shapes how we do science, but the nature of scientific outcomes too; using philosophy to improve practical communication; facilitating thoughtful debate on the potential dangers of Norway joining the European Union; or discussing the ethics of climbing, the meanings of sustainable development, or distinctions between different approaches for addressing the ecological crisis, Naess seamlessly connects philosophical questioning to activeness in relation to the questions.

SERIES EDITOR'S INTRODUCTION

Naess's philosophical career can be seen, in one sense, as an attempt to bridge C. P. Snow's two cultures. Believing that the central questions of philosophy are here to stay, he has developed his philosophy over seventy years in part through his effort to relate these questions to the issues of his rapidly changing, trying, and tumultuous era. Naess's lifelong commitment to integrate interests in nature, science, and logic is evidenced by the mature Naess's championing of philosophical approaches in which both metaphysics and science contribute to all-embracing systems of thought. This approach is particularly prominent in Naess's development of normative systems theory, a strategy for promoting systematic reflection on premises and conclusions. Recognizing that all philosophical questioning must stop somewhere, Naess calls the essential intuitions that serve as bedrock assumptions for our total views, ultimate norms or ultimate premises. Further, recognizing that our philosophical conclusions as well as our lifestyles and everyday actions often appear inconsistent with these ultimate premises, Naess has developed a strategy for using premise-conclusion strings to help identify potential norm conflicts as well as to help assess whether potential agreements and disagreements are real or pseudo. Use of this technique figures prominently in Naess's approach for improving communication, in his approach for exploring both the philosophical basis for Gandhi's *satyāgraha* (active nonviolent resistance) and the Gandhian premise "Any human conflict can be justifiably resolved through nonviolence," as well as in his own Ecosophy T.⁸

With regard to total views—broad philosophical systems like Spinoza's, which attempt to communicate our deepest insights and communicate views of life—Naess argues that although the existence of complete, explicit total views is absurd, it is equally absurd to presume to criticize a total view without adopting one (at least implicitly). After relinquishing the possibility of creating a consistent empirical theory of knowledge, Naess came to believe that any theory of knowledge presupposes all major philosophical disciplines, at least on the metalevel. One cannot have a theory of knowledge without presuming a particular reality, at least implicitly, and this necessitates having an ontology, metaphysics, ethics, and so on. This has practical consequences too. We never simply act solely as a philosophy professor who specializes in logic or ethics; we are always, at least partly, mother, daughter, lover, scientist, . . . , and philosopher. If we accept

SERIES EDITOR'S INTRODUCTION

the premise “For every decision we, explicitly or implicitly, take all things into consideration,” then the notion of total views or total normative systems can be seen as very “useful fictions,” which, if articulated, might help us to improve decision making.

Naess is careful to point out that he sees his own total view and others as fragmentary and constantly evolving—ever “on the way.” Moreover, even if we could have a completely formed and integrated total view, we could not count on being able to articulate it. There will always be a tension between the Spinozistic goal of clarity and the pragmatic reality that in this world we can never wait until all the facts are in. None of these issues, however, justifies abdicating our responsibility to try to articulate our own total views. The mature Naess is a radical pluralist. He believes in defending coherent systems, without claiming that their relation to reality is definitive. While he is committed to the importance of models and systems, he is opposed to the idea that there could or should be a definite worldview. Naess’s hope is that there will be no definite scientific worldview in the future.

No Western philosopher since Descartes—except perhaps Spinoza, who has also been a primary inspiration for Naess—has had the potential to help us drastically reshape our relationship to each other and life in general: not by spelling out *a* clear and coherent total system—to be taken as *the* truth—but by challenging us to articulate our fragmentary total views and connect the abstract problems of philosophy to issues of contemporary social and political conflict. In Naess’s view, “[t]he full meaning of a theory can only reveal itself in practice, and practice is blind without theory.”⁹ To be a philosopher of life, one must embrace both theory and practice and engage them in dance.

In Norway, Arne Naess is regarded as a national treasure, a seeker and a seer, a “minor prophet,” in his own words. His radical pluralism and endorsement of diversity are demonstrated by his complex character. He has a proclivity for being aloof and charming, somber and joyful, accountable and carefree, arrogant and modest, slippery and precise. In a world of contradictions—breathtaking beauty *and* ineffable squalor and suffering—Naess is no exception. He is an antiguru guru. He strives for high levels of consistency and integration in his philosophy but accepts that in his personal life he cannot live up to his philosophical systems’ requirements. He strives for definite-

ness of intention, yet he appreciates vagueness and eschews dogma, refusing to be pinned down to a particular viewpoint or placed in a particular philosophical camp. This stance is further supported by his sometimes maddening tendency to revise, revise, and re-revise. As a consequence, one cannot go to any of his books or articles and find the “definitive” Arne Naess. He is a troublemaker too, but the kind of troublemaker people want to have around because he challenges orthodoxies with an elfin irreverence. Naess stands out because his frequently outlandish and controversial views are felt deeply, reasoned carefully, and conveyed playfully.

Naess has had a profound influence on Norwegian academic life and the society as a whole. From 1939 to 1954 he was Norway's only professor of philosophy. He was chiefly responsible for organizing courses for the *examen philosophicum*, introductory examinations in logic, methodology, and history of philosophy that an entire generation of undergraduates (roughly 100,000 people) were required to take, regardless of their disciplinary focus. His unique paradigm of inquiry—emphasizing open-mindedness, empirical analysis, pluralism, a thorough grounding in philosophy and the history of ideas, and a vital concern for contemporary problems—is credited with shaping the intellectual fabric of postwar Norway. At a press conference for Naess's eightieth birthday, the Norwegian Minister of Education testified to the significance of the Norwegian version of Naess's *Communication and Argument*, one of the primary texts for the *examen philosophicum*. “We have all read it. We *still* cheat in argumentation, but now with feelings of guilt.”¹⁰

Naess is also credited with rekindling the study of philosophy in Norway and with forming the Oslo school of philosophy. The section on Scandinavian philosophy in *The Encyclopedia of Philosophy* elaborates:¹¹

The philosophical milieu in Norway today [circa 1967] is determined by an internationally known and original philosopher. . . . Arne Naess . . . is the originator of a radical type of empirical semantics and the leader of the so-called Oslo group. . . . The empirical methods applied by the Oslo group employ carefully worked-out questionnaires. By the help of such questionnaires and by teamwork, philosophers of the Oslo group have carried out investigations of such expressions as “truth,” “democracy,” and “private enterprise.” . . . If it is correct that Norwegian philosophy has had a dead period,¹² it is equally correct to assert that, primarily because of Arne Naess, Norwegian philosophy is now in the middle of a period of life and growth.

SERIES EDITOR'S INTRODUCTION

When asked to comment on this passage, Naess was emphatic about inserting an addendum to the last sentence.¹³ He was proud to convey that contemporary Norwegian philosophers pursue a wide variety of directions and employ a diversity of approaches, many independent of Naess's own line. This point is borne out by the more than forty-four permanent teaching positions currently at the University of Oslo's Institute of Philosophy and the broad spectrum of approaches these philosophers pursue, from the analytic tradition to phenomenology and from existentialism to hermeneutics. As one of Naess's successors, Alastair Hannay, in his section on Norwegian philosophy in the *Oxford Companion to Philosophy*, has commented, "Norway enjoys a varied and vigorous philosophical life. . . . Philosophy's place in Norwegian academic life, as in the society at large, is due in large measure to Naess."¹⁴

The reach of Naess's contributions to philosophy and social research extends well beyond Norway. Significant international recognition has also come his way for these contributions. He has received the Peer Gynt Prize awarded by the Norwegian Parliament (2004), the Nature and Environment Prize from the Nordic Council (2002), the Nordic Prize from the Swedish Academy (1996), the Mahatma Gandhi Prize for Non-violent Peace (1994), and the Sonning Prize for contributions to European culture—Denmark's version of the Nobel Prize (1977). He has even been honored by five festschrifts, one each for the occasions of his seventieth, eightieth, and eighty-second birthdays and two for his eighty-fifth birthday.¹⁵ He is the founding editor of the influential journal, *Inquiry*, created to promote collaboration between philosophers and social scientists. He is also a renowned mountaineer and climber, an occasional nonviolent political activist, and father of the deep ecology movement. His social concern, sense of wonder, and trickster nature have all contributed to his success at numerous academic posts around the world—preferably near mountains or deserts—from Berkeley to Jerusalem and Helsinki to Hangzhou. He is, to this day, still a frequent international speaker.

Even with this high level of accomplishment, the significance of his work as a whole—as a gestalt—has yet to receive broad-scale appreciation outside of Scandinavia. There are many explanations for this situation.

The overarching reason has likely been the general inaccessibility of his oeuvre. This inaccessibility has many facets. Naess has been incredibly pro-

SERIES EDITOR'S INTRODUCTION

lific, producing over four hundred publications, more than thirty of which are books. These publications span topics from argumentation theory to zeteticism, with adventures along the way at such seemingly incongruous destinations as climbing ethics, cultural anthropology, and deep ecology. His range of topics—in abundance, breadth, and depth—is trying, at best, for our increasingly compartmentalized and specialized academic communities.

In addition, the bulk of his most significant works have been out of print for quite some time. Many of the earlier editions of the books were edited poorly and documented sparsely. A significant portion of his important articles and book chapters appears in obscure or difficult-to-find books and journals, and much of his work has remained unpublished (at least two hundred papers and several book-length manuscripts). Naess's main works appear in three primary languages, German, Norwegian, and English, although he has also written in Danish, Swedish, and French. Finally, Naess's prose can be dense and opaque, if not downright confusing. Although this trait is by no means unusual for a philosopher, when blended with Naess's appreciation for vagueness and ambiguity, his aversion to authoritative stances, and his tendency to revisit topics by reconsidering earlier viewpoints, the already high entrance fee can become prohibitive.

The boundless range of Naess's interests and the general inaccessibility of his entire oeuvre have led some scholars to view him rather pejoratively as a dilettante. Some of these critics view him as flitting from one area of interest to another, not mining any to its logical conclusion; some see him as throwing away a great talent in logic; some view his social research, especially his work with questionnaires on lay people's and experts' perceptions of philosophical concepts and his use of statistics, as outside the realm of serious, professional philosophy; and still others see him as inappropriately conjoining his philosophy with activism. His breadth has even led a few of the more extreme critics to dismiss his work out of hand. Although some of the criticisms detailed above do have merit, in my view Naess gives the dilettante a good name.

To address this range of concerns, the *Selected Works* project was conceived. The project was the brainchild of Douglas Tompkins. "Miracle Doug," as Arne refers to him, is the founder of the Foundation for Deep Ecology and is himself a renowned climber and kayaker in addition to being a wildlands philanthropist who has helped protect immense tracts of

SERIES EDITOR'S INTRODUCTION

land in Chile and Argentina, some as large as Yosemite. The *Selected Works* would have simply remained a “great idea” without Doug’s generosity and support. The project was initiated in 1994 and commenced editorial work in 1996 under my direction.

In the introduction to his *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, and Sartre* (1968), Naess decries the condition whereby the philosophical life of an individual is set by the local philosophical scene, by provincial biases, or by what is easily accessible.¹⁶ Such accidents of environment should not, in Naess’s view, play a pivotal role in shaping a budding philosopher’s development. I see the *Selected Works*, at least in part, as a response to this predicament.

The purpose of the *Selected Works* is to bring—for the first time—the full scope of Naess’s philosophical contributions to the English-language audience in one collection of highly readable and meticulously edited volumes that adhere to the highest standards of contemporary academic philosophical publishing. The *Selected Works* is, however, by no means exhaustive; it is not a collected works.¹⁷ We have simply aspired through careful selection to offer a representative and relatively expansive collection of Naess’s principal writings. As such, the *Selected Works* is the definitive repository of Naess’s oeuvre, chronicling the development and progression of his thinking for scholars, students, and critics alike.

In the remainder of this essay, I attempt to sketch briefly one possible version of an intellectual biography for Arne Naess. I endeavor to trace some key influences on Naess’s philosophical development, discuss the evolution of his philosophical outlook, and touch on the relevance and significance of each volume in the *Selected Works*. I close with a short note on our editorial approach.

From Scientism to Wisdom: Toward a Philosophy of Life

The philosophic researcher should be task-minded, not discipline-minded,
and should follow his questions wherever they lead.

Arne Naess, “Norway”

Arne Dekke Eide Naess was born in 1912 in the dining room of a large house with a wild, expansive garden. The house was on the outskirts of Oslo in Slemdal, a short walk from where Naess lives today. Arne was the

SERIES EDITOR'S INTRODUCTION

unplanned fourth child of a wealthy family from Bergen. Before he was a year old, his father, who was ill with cancer, had died. Overwhelmed, his mother, Christine, entrusted little Arne to the family's governess. This is where his first memories begin.

Arne speaks of Mina, his governess, endearingly. She is described as satisfying little Arne's every wish, be it procuring live flies for his bath or bringing a trunk filled with bottles on a family trip so that he could continue his water-play experiments. Sometime before Arne was four, Christine dismissed Mina, ostensibly for spoiling Arne too much. This initiated a deep rift between Arne and his mother, which was never to be mended. It also set in place a sense of loss, alienation, and resistance to emotion that profoundly influenced Naess's early personal and philosophical development.

Significantly later, after an intensive six-day-a-week, fourteen-month psychoanalysis with Freud's noted collaborator Dr. Edvard Hitschmann, Naess came to understand his impenetrable shell that keeps others at arm's length (*Panzercharakter*, in Freudian terms) as resulting from a reaction to his mother's unreliability and emotional hysteria. His effort to keep his mother at a distance morphed into a general aloofness and distancing. The adolescent Arne began to favor an "objective," bureaucratic approach to language. He saw art, music, and poetry as being seduced by emotion, by beauty and form, but viewed science and philosophy as realms from which such emotions should be banished. This prejudice would take decades to overthrow. At this time he also developed a single-mindedness and resistance to inconvenience and pain that to this day make it easier for him to concentrate and focus. As Hitschmann pointed out, however, this inward turn has a flip side, a certain self-destructive or masochistic bent that was later to plague him, particularly in his relationships with women and his children.

Much of Arne's early childhood was spent at the seashore, and this is the period in which his interest in nature and experimentation began to flourish. Feeling somewhat distanced in his relations with people, he identified with nature, especially little sea creatures. He waded in shallow water for hours, inventing experiments to test nascent hypotheses about the behavior of small sole, tiny translucent shrimp, and crabs. He describes these experiments as engendering an early enthusiasm for diversity and a tendency to suspend judgment on the nobility or status of different beings. He

SERIES EDITOR'S INTRODUCTION

loved these creatures for their unique qualities and their amusing adaptations and limitations. They inspired a certain egalitarianism, which took hold and later influenced his philosophical approach in profound ways.

Young Arne was restless. He had an early penchant for “collecting” and organizing large groups of numbers, stones, and stamps. He started climbing trees in the family’s little “wilderness” before he was five and soon progressed to big firs and spruces. He found that he enjoyed being able to watch people from above. Arne outgrew trees fast. His desire for perspective and the opportunity to survey broad areas was rapidly transferred to mountains. At the age of five, he began going to his mother’s small mountain cottage in the town of Ustaoset, high in the Hardangervidda between Oslo and Bergen. By the age of eight, he had adopted Hallingskarvet, a bread-loaf-shaped mountain about three and a half hours’ walk from Ustaoset, as his surrogate father. In his teenage years, this obsession for expansive perspectives translated into a lifelong passion for mountaineering. When Naess was sixteen or seventeen he climbed the 106 tallest mountains in Norway. It was around this time that he was first introduced to Spinoza’s *Ethics* by a Norwegian Supreme Court justice that he met in the mountains. Naess’s desire for a broad and open perspective, for seeing things in totalities (god’s-eye view), translated to his studies. Young Naess read widely in economics (especially value theory), science, philosophy, history of philosophy, and the Earth’s biological history.¹⁸ This commitment to cultivate an ever-expanding perspective would later potentially influence his approach to philosophy.

Arne’s youth was spent captivated by piano, study, and mountains. His decade-older brothers took it upon themselves to toughen up their timid younger brother, as well as introduce him to the ways of the world and scholarship. When Arne was only eight, his eldest brother, Ragnar, left for America to study for a Ph.D. in chemistry at MIT. Ragnar later went on to receive one of the Harvard Business School’s first degrees and became a successful stockbroker in the United States. Erling studied economics and went on to create an international shipping empire; he became famous for his assistance to the Norwegian government-in-exile during the Nazi occupation. His sister, Kiki, married a German doctor and after the Second World War returned to Norway to become a physical therapist. From Kiki he learned the power and significance of offering encouragement to others.

SERIES EDITOR'S INTRODUCTION

During his early years and well into adulthood, Arne's tight-knit relationship with his siblings provided security and support for him to "find his own way" — *sva mārga*, to use one of his favorite Sanskrit terms. Although he tended not to seek their financial assistance, his wealthy and generous brothers offered a sense of comfort, safety, and the occasional extravagance, which in later life made it easier for him to live his bon mot, "simple means, rich ends."

Naess studied philosophy, mathematics, and astronomy at the University of Oslo. At nineteen, after completing the equivalent of an undergraduate degree, he left Oslo to continue his studies in Paris. Naess was put off by the adoration Bergson received in Paris, but ultimately left to seek broader vantage points, cheaper living, and better climbing opportunities. After completing two master's theses at twenty-one, one exploring discussion about the concept of truth and the other exploring the use of behavioral psychological principles to judge truth validity, Naess left Oslo again, this time for Vienna. In Vienna he took master classes in piano, where, following his trickster nature and as a response to the strict taskmaster Fuchs, he "learned" new material. When he ran out of pieces he had long since mastered, he quit. Thinking that it was necessary for philosophers to have high levels of self-knowledge, he underwent intensive psychoanalysis with Dr. Edvard Hitschmann. As a part of that process he assisted with the treatment of patients in a psychiatric hospital and developed tremendous empathy for the suffering of humankind. While in Vienna, he was also warmly welcomed at the famous Schlick seminar.

The logical empiricists' friendly, equiminded approach to discussion made a great impression on Naess, but he was not equally affected by their ideas.¹⁹ The young Arne was impressed by the preciseness, empirical nature, and lack of emotion in science—he wanted to practice philosophy with a scientific bent and he wanted to test philosophical hypotheses with experiments. He was already interested in perennial philosophical problems and did not believe that most of them were ultimately pseudoproblems that could be solved by investigating inconsistencies in language. His most significant philosophical issue with the logical empiricists was not that they were empirical, although he believed they were misguided in thinking that any philosophical problem could be wholly empirical, but that they were ultimately antiempirical in their belief that a logical gram-

SERIES EDITOR'S INTRODUCTION

mar of language was more suitable for investigating the use of terms than statistical analysis of their actual use. Naess's detailed critique of the logical empiricists' position and reflections on his personal experiences attending the Schlick seminar appear in volume VIII. In this critique, Naess expresses a concern that in their interpretation of terms, many philosophers (not just the logical empiricists) were artificially constricting the range of possible interpretations and thus unintentionally reducing potential insights regarding the diversity of tenable positions on problems of vital concern. This perspective presaged his later views, particularly those expressed in *Interpretation and Preciseness* (SWAN I), and his later approach to cultural anthropology and philosophy of science. Naess sums up his general perspective on the state of philosophy at the time with the following remark: "The turn of (Western) philosophy in [the twentieth century] towards language rather than cosmos, towards logic rather than experience in the broadest sense (like that of William James), is a turn into a vast blind-alley."²⁰

While in Vienna for fourteen months in 1934 and 1935, Naess made final revisions to his doctoral thesis, *Erkenntnis und Wissenschaftliches Verhalten* (Knowledge and scientific behavior).²¹ Although Naess drew inspiration early on from Russell and Whitehead, his doctoral thesis can be seen, in part, as support of the American Pragmatists (James and Dewey) in opposition to Russell and early Wittgenstein. According to Dewey, the main purpose of his philosophical writings was "to reintegrate human knowledge and activity in the general framework of reality and natural processes."²² Naess did just this by creating a radical and unique approach for exploring how high science is performed, a sort of science of science. At this point, Naess believed it was possible to use such an approach to obtain a complete account of all science within one system. Inspired by the ethologist Uexküll's "special biology" (*Umweltforschung*), Tolman's "objective" behavioral psychology ("molar" behaviorism), and the cultural anthropologist Malinowski's work on speech and nonverbal behavior, Naess took on the standpoint of a neutral, nonparticipant spectator and outlined a program for an empirical metascience of science, an ethological approach to epistemology of science.

Naess used the idea of a dispassionate visitor from another solar system coming to study Earth-based scientists to demonstrate the possibility of completely describing both the activity of researchers and the contents of

knowledge without drawing on the subjective models that governed traditional epistemology and presupposed knowing subjects or minds. The idea was to study or rather “witness” science similar to the way experimental psychologists study rats, but without falling into the trap of imposing their own experience of reality and their preexisting conceptual models of reality (“maze epistemology”), or their scientific pretensions. In the view described in *Erkenntnis*, knowledge is cognition—it is an activity with intention—and this helps to dismantle the subjectivist dualism between the content of knowledge and the activity of research. Naess’s interest was in describing these patterns of research activity. He argued that the *terminology* associated with scientific activity—which is bound to the subjective-reality model—changes in leaps and bounds, not the *patterns of research activity*, which are in constant, but gradual, flux. With this argument that change in science happens gradually, by generalization and differentiation, Naess foreshadowed his response to Kuhn well before *The Structure of Scientific Revolutions* was published in 1962.

With *Erkenntnis*, Naess also anticipated ideas that later became prominent in linguistic philosophy, such as the importance of ordinary language over formal systems and the importance of using observation of contrasts and discriminations to build up understanding of systems. In the end, presaging his own radical pluralism to come, Naess seems to relax his early position on the importance and possibility of creating a metascience of science from the “far outside” and ultimately comes to view subjective and behavioral models as two different point-of-departure formulations in an indefinite plurality of equally valid approaches for a metascience of science. This refined perspective is taken up in Naess’s 1965 article “Science as behavior” (in SWAN IX), which returns to the prospects and limitations of creating a behavioral metascience to study the scientific enterprise, but this time from the “near outside.”

At age twenty-four, after receiving his Ph.D. from the University of Oslo for his work on science as behavior, Naess returned to his interest in the problem of truth. A particular concern was the inadequacy of philosophers’ intuitive methods for capturing how lay people conceived and used the term *true*. In 1937 and 1938 he developed and tested an empirical approach for using questionnaires and statistical analysis to investigate non-philosophers “commonsense” views on the notion of truth. He then related

SERIES EDITOR'S INTRODUCTION

these notions to philosophers' theories of truth. Naess found an amazing diversity of views among the amateurs. He also found that their views, although typically devoid of philosophical pretensions, generally covered the views represented by professional philosophers. This work elicited substantial controversy, most of which came from philosophers who viewed it as undignified to use questionnaires and statistics to investigate one of the great problems of humanity. Naess's results were published as *"Truth" as Conceived by Those Who Are Not Professional Philosophers* (1938). A summary of this work is presented in Naess's "Common Sense and Truth" (in SWAN VIII). Naess's continued application and refinement of these techniques would evolve into empirical semantics.

In 1937 Naess fortified his lifelong fascination with the arctic climate Hallingskarvet by building Tvergastein, his now-famous rustic and remote hut, at its base, a three-and-a-half-hour trek from the train station at Ustaaset. He outfitted the hut with Rube Goldberg oil lamps that also served as stoves for warming tea and with an eclectic library of teach-yourself language manuals, Sanskrit-English dictionaries, astronomical and wildlife field guides, novels by Dostoyevsky and Ibsen, letters of Spinoza, and a complete philosophy library. Following his passion for amateur science he also created "institutes" of petrology, chemistry, zoology, hydrology, and botany at Tvergastein. Naess has written the bulk of his work at Tvergastein and spent the equivalent of about twelve of his ninety-two years living there. The enormous open views at Tvergastein afforded Naess the distance and perspective he so craved while insulating him from philosophic fashion and dogma. Here he had the luxury, freedom, and good fortune to pursue his own interests free from the banalities and distractions of academic life. After completing what is now Tvergastein's main room, Naess went on to perform postdoctoral research at Berkeley (1938–39) with the pioneer of empirical psychology, E. C. Tolman. At Berkeley, he went from studying the behavior of rats faced with many possible alternatives to studying the behavior of the scientists studying the rats.

Naess returned to Oslo in 1939 to be appointed to the University of Oslo's Chair of Philosophy at the age of twenty-seven. On April 9, 1940, German forces invaded Norway; it would remain under Nazi rule for the next five years. This was a harrowing time for academics throughout Europe. Arne tried to maintain his unruffledness, pouring himself into re-

SERIES EDITOR'S INTRODUCTION

search and curricular reform initiatives intended to widen and expand the perspective of university undergraduates. He tried to stay at Tvergastein often, and this afforded him some peace and solace in a world of great tension. Before long, however, even he was drawn into the resistance movement. In the fall of 1943 he played a central role in foiling a Nazi attempt to deport University of Oslo students to concentration camps for “reeducation.” The University was subsequently closed and Naess became even more committed to the resistance movement and his research. By this time he had developed great admiration for Gandhi’s catalytic 1930 *satyāgraha* campaign, the march to Dandi in protest of the British salt tax. Naess was greatly impressed with Gandhi’s idea of trying to meet one’s opponent in a manner that would calm passions and facilitate truthful communication. He thought such an approach could have had a significant effect on quenching the Nazi expansion, *if* the necessary infrastructure to support *satyāgraha* had been created in European countries. After the war, Naess used these insights in his efforts to bring together suspected torturers and the families of torture victims to gain a sense of closure on the fate of their loved ones—and to avoid having the “traitors” subjected to equally horrid persecution. In 1948 Naess was invited to be the scientific leader of a new UNESCO project created to explore ideological controversies between the East and the West. He was soon off to Paris again, this time to pursue his interest in using philosophy to address questions of social and political importance.

The Cold War was a tinderbox and two core ideological conflicts revolved around use of the terms *democracy* and *freedom*. Naess was asked to address both but countered that UNESCO’s requirement that he deliver a report within one year made it essential for him to consider *democracy* first. His goals were to clarify what people mean when they use the term *democracy* and to understand the causes of ambiguity and confusion that result from its use. After an extensive literature review, which chronicled historical usage of the term, Naess and his assistant, Stein Rokkan, prepared a thirty-question survey that was distributed to almost 600 international experts in the fields of philosophy, law, history, political science, sociology, economics, communications, and logic. Naess used the roughly 100 replies to create an empirical study of “agreements” and “disagreements.” The study demonstrated *democracy*’s richness, diversity, and multiplicity of

SERIES EDITOR'S INTRODUCTION

meanings and thus undermined its misuse in both the East and the West. This incited detractors from every ideology, who roundly criticized the resulting report, *Democracy in a World of Tensions*, which according to Naess “was promptly sold out and never reprinted by UNESCO due to the politically dangerous character of its items.”²³ Naess’s “Analytical Survey of Agreements and Disagreements,” along with two other pieces on ideological convictions and rationality, appears in SWAN IX.

The UNESCO democracy study was the first and last international, large-scale application of Naess’s empirical semantics approach. He was originally interested in doing another study on “cultural diversity,” but neither this nor the “freedom” study came to fruition. Naess learned—much to his chagrin, and as his superiors had warned—that UNESCO was a place for writing reports; it was no place for conducting research. Naess’s frustration with the UNESCO experience and his wanderlust for the perspective of mountains led him to daydream first, and then to “pursue non-essentials”:²⁴

The arguments against abandoning the imaginary joys of the Himalayas for an actual expedition seemed strong to me, and so they still do. But in the autumn of 1948 the longing for the mountains pushed aside all sensible considerations. For the first time since I was twelve years old, I had to do without a summer holiday in the mountains. The safety valve guarding one against exaggerated climbing expeditions was thus removed. Added to this came the great disappointment in my own work. Lured by UNESCO’s plans of philosophical research into international ideological conflicts, I had been tied up in Paris for nine months. Such large-scale extravagant schemes prove, however, impracticable. Too much nationalism and too little belief in research prevented UNESCO from getting the number of nations to subscribe to such long term schemes. By the way of compensation, I indulged at night in delightful trips to the Alps. As the situation got worse, this was, however, not sufficient compensation; the material was exhausted. Then my fantasies took me to the Caucasus. Later I had to go all the way to Persia, Afghanistan, Hindu Kush and India, and so I was committed.²⁵

Although Naess’s research interests and total view continued to evolve after 1953, the general philosophical approach of the mature Naess, outlined at the beginning of this essay, was basically in place. Naess has described his

philosophical work as falling into four periods or phases. From the mid-1930s until about 1940, he focused on philosophy of science. Then until about 1953, he concentrated on empirical semantics. A short period, surrounding the publication in 1968 of his major work on the zetetic scepticism of Pyrrho, ends when, at the pinnacle of his philosophical career, he sought early retirement in 1969 to devote himself more fully to ecological issues and activism. Naess has commented that this effort to be more actively engaged in social and political conflicts reflects his desire "to live rather than function." This view adequately reflects coarse, general trends, but it fails to do justice to Naess's philosophical approach, which has him mine a larger range of topics and return to them in a helical fashion throughout his life. I would rather describe his work as falling into thematic areas that were picked up, sometimes put on ice, but returned to periodically throughout his life. Although I concur that the period after his formal retirement can be seen as emphasizing ecological philosophy and activism, the two decades between 1960 and 1980 also represent a period of considerable productivity on conventional academic philosophical topics. It was in those decades that Naess produced important work, especially, on scientific and cultural pluralism, Gandhi and Spinoza scholarship, history of philosophy and philosophy education, and normative systems theory. He has written on a wide range of important philosophical topics even into the 1990s and beyond, during which time he produced, among other works, his *Life's Philosophy* (2002; coauthored with Per Ingvar Haukeland), introductions to the philosophy of Gandhi (2000) and Spinoza (1999), and *Introduction to General Relativity and Its Mathematics* (1998; coauthored with Øyvind Grøn).²⁶ An adequate sketch of Naess's subsequent research interests and philosophical development can be gleaned from the following brief discussion of the volumes in the *Selected Works* and the discussion, at the end, of how his earlier work figures into the evolution and exegesis of deep ecology.

Naess's best-known philosophical work is likely *Interpretation and Preciseness*, published in 1953 (SWAN I). It is an attempt to convince the world of analytical philosophy about the types of approaches that are necessary, from the standpoint of a radical empiricist, to adequately interpret terms and point-of-departure statements (T_0 statements), given the manifold of plausible interpretations. It highlights the role and potential of experience in relation to intuition and reflection by requiring that every direct or im-

SERIES EDITOR'S INTRODUCTION

plied hypothesis regarding the actual use of terms, phrases, or sentences be testable. In addition, it responds to the ostensibly antiphilosophical sentiment in *Erkenntnis* by clarifying the function of and relationship between point-of-departure statements and precizations. In Naess's semantics, the most general statements, T_0 statements (words or sentences), are phrased in ordinary language and are intended to be philosophically neutral. T_0 statements serve as points of departure for investigations of possible interpretations. When a new interpretation of an expression eliminates some of the ambiguity of a preceding interpretation, without adding any new ambiguity, it is said to be a "precization." Thus, a sentence T_1 is more precise than a sentence T_0 when every plausible interpretation of T_1 is also a plausible interpretation of T_0 but at least one plausible interpretation of T_0 is not a plausible interpretation of T_1 . This process of using successive differentiation to better understand people's interpretations of terms, phrases, or sentences can go on almost ad infinitum; it is limited only by time, resources, imagination, and willing test subjects. With this process, however, Naess has created a formal approach for classifying different statements (interpretations) based on users' "depth of intention," the point at which they no longer, explicitly or implicitly, accept or embrace higher levels of precization. A focal point is Naess's approach of directly employing surveys to explore systematically and empirically the meanings of terms, phrases, or sentences based on their occurrences. Naess also created a formal procedure for comparing occurrences, both interpersonal and intrapersonal, that involves performing tests for different forms of synonymy. Naess has applied his empirical semantics approach to explore the meanings of "truth," "democracy," "it is the case," "certain," "perfectly certain," and "extremely probable" (see SWAN VIII for additional details on and applications of empirical semantics).

In *Scepticism* (SWAN II), published in 1968, Naess takes on the generally accepted position that scepticism, if widely embraced, leads to the intuitively false conclusion that we cannot know anything. Naess explores the variety of historical interpretations of scepticism in light of Sextus Empiricus's outline of Pyrrhonian scepticism. Three categories of philosophical positions on the question of truth are considered: Dogmatists claim at least one truth, Academicians negate the possibility of finding any truths, and Pyrrhonists neither assert that they have found any truths nor assert the impossibility of finding one. Naess takes a sympathetic view of this last

group, arguing that this form of zeteticism can represent both a viable philosophical position and a way of life that supports positive mental health. What ultimately sets this position apart is not that supporters are fundamentally opposed to making acts of assertion, to stating that "something is the case," but that they do not make such assertions with the conviction of truth. Naess also uses empirical semantics to demonstrate support for this position on rational and epistemological grounds. Distinguishing between one's philosophical view and the necessity of firm, socially responsible action in everyday life, he also responds to the common notion that this radical nondogmatism generally leads to paralysis of action. In the end, Naess argues that adopting this updated view of Pyrrhonic scepticism could lead to quite the opposite, a more open-minded approach to philosophy and life. Further elaborations on particular aspects of Naess's Pyrrhonism along with a response to Rescher's reappraisal of scepticism appear in SWAN VIII.

Which World Is the Real One? (SWAN III), which was first published in 1969 and revised in 1982, is, in part, an attempt to reinvigorate appreciation and study of the broad variety of philosophical outlooks and total views that exist in Chinese, Indian, Greek, Western, comparative, and recent philosophy. It makes use of Naess's empirical semantics, developed in *Interpretation and Preciseness*, to argue that it is an illusion to assert that combined scientific and philosophical or "purely" philosophical syntheses of such total views can exist. Naess argues that the results of science cannot be integrated into any single world picture, in part because such attempts at synthesis are necessarily fragmentary and because valid multiplicities of syntheses exist. He also takes up the question of the comparability of total views. Such comparisons, although important, are inevitably shaky because, despite admirable aspirations for standing back to obtain a meta-perspective, real people can never totally throw off their own total views; regardless of how explicit those views may be or of how conscious of them their holders are, biases are unavoidable. We always have our own perspective to contend with. For Naess the inevitable conclusion is that pluralism is inescapable and nothing to lament. He combines these points of view with a discussion of cultural anthropology to argue for the critical importance of supporting the flourishing of rich cultural diversity. Additional articles elaborating themes related to the significance of maintaining cultural diversity and its relationship to ecological sustainability appear in SWAN X.

In *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN

SERIES EDITOR'S INTRODUCTION

IV), published in 1972, Naess suggests that scientific theories must be understood in the wider context of the plural rationalities from which they spring. Science is not autonomous. Nor can it be seen justifiably as arising independently from the general enterprise of building philosophical systems. Furthermore, the relationship of models to reality is always indirect. This volume should be seen as an effort to erode the popular misconception of science as infallible and a viable surrogate for religion, not as an attempt to build a unified theory of science within one system, which Naess had long since rejected. Because no theory can ever be either fully verified or falsified, there exists a significant freedom of choice in both modes of exploration and theories that one can tentatively adopt. The notion of “fundamental theories” is immediately called into question. As the undemonstrated (and often undemonstrable) assumptions upon which theories rest are changed, a huge multiplicity of possibilities for future theory development arises, thus possibly helping to inspire a renewed enthusiasm in science by broadening our concept of rationality and restoring the role of imagination. Articles extending or elaborating on the ideas in *The Pluralist and Possibilist Aspect of the Scientific Enterprise* appear in SWAN IX.

Naess's third book on Gandhi, *Gandhi and Group Conflict* (SWAN V), was published in 1974. This book develops an intellectually rigorous presentation of the theory of *satyāgraha*—the way of militant nonviolent resistance—as a strategy for conflict resolution. This work is a paradigmatic example of Naess's approach to research and writing. As the eminent Norwegian social scientist and peace researcher Johan Galtung has suggested, Naess's 1955 *Gandhis Politiske Etikk* (Gandhi's political ethics)—with Galtung—and his 1965 *Gandhi and the Nuclear Age*, along with his articles that analyze or extend on Gandhi's work (see SWAN IX and X), act as exercises or drafts for this, his major work on Gandhi.²⁷ Using Gandhi's own recorded accounts, Naess explores the norms and hypotheses tacitly employed by Gandhi in his nonviolent campaigns and then uses these to create the first philosophical and logical systematization of Gandhi's approach to militant nonviolence. A careful investigation of Gandhi's two ultimate norms (as interpreted by Naess), “Seek complete self-realization” and “Seek truth,” and his belief in *advaita* (nonduality), along with a consideration of their parallels to Spinoza's unity thesis, will reveal interesting insights into Naess own characterization and use of “Self-realization!” as

the single ultimate norm of his Ecosophy T. Naess also considers Gandhi's approach to nonviolent conflict resolution in light of contemporary reactions against the use of nonviolence by Frantz Fanon, Malcolm X, Stokley Carmichael, C. V. Hamilton, and Sartre. He then examines Gandhi's ideas and intentions regarding group conflict in light of the ideas and intentions underlying other modern philosophies of conflict, including those of Luther, Nietzsche, Tolstoy, and Jaspers.

In *Freedom, Emotion, and Self-Subsistence: The Structure of a Central Part of Spinoza's Ethics* (SWAN VI), Naess uses symbolic logic to present a formalization and partial reconstruction of a small but important part of the *Ethics*. Spinoza's system is embedded in the seventeenth century and expressed in Medieval Latin. Two of Naess's goals are to bring empirical analysis to bear in trying to interpret and update Spinoza's system and to make Spinoza's insights more accessible and relevant to contemporary readers. To perform his reconstruction, Naess draws heavily on a small book he produced in 1962, *Equivalent Terms and Notions in Spinoza's Ethics*, which lists and discusses 243 equivalences that are directly asserted or suggested by Spinoza in the *Ethics*, according to Naess.²⁸ Accepting the transitivity of the equivalence relations as a general rule, Naess argues that a vast array of structural relations can be elucidated (many of these are often only suggested or implicitly asserted by Spinoza). One of Naess's key conclusions is that every living thing is to some extent "in itself" and to some extent "in something else" due to the presumed gestalt nature of reality. Another is that the terms *substance*, *attribute*, *God*, *mode*, and *Nature* are "expendable"; Spinoza's basic nondualism is made clearer by Naess. A third conclusion is that *to be active* and *to understand* cannot be systematically distinguished in the *Ethics*. This notion, which has important implications for philosophy of science, is also embedded in Naess's conclusion in *Erkenntnis* that knowledge is cognition—the content of knowledge and the activity of research cannot be cleanly separated. Naess uses his analysis to explicate three main themes of Spinoza's system: the importance of a notion of uncoerced freedom (not coerced by externals), the importance of developing and acting on strong emotions to make progress in achieving higher levels of freedom, and the importance of joy that activates the complete person (as opposed to joy that simply activates part of the body or the soul). By clarifying the semantic structure of a central part of the *Ethics* with his own logical struc-

SERIES EDITOR'S INTRODUCTION

ture, Naess explains that there exists a wide variety of possible interpretations of the contents of the *Ethics*. Articles on Spinoza's determinism and its relationship to freedom, Spinoza and Māhāyana Buddhism, "Spinoza's Finite God," and other Spinoza-related topics appear in SWAN IX. Articles that explore Spinoza as an inspiration for deep ecology appear in SWAN X.

The English translation of *Communication and Argument: Elements of Applied Semantics* (SWAN VII), which was first published in 1966, is largely a popularization of the central ideas in *Interpretation and Preciseness*. The English edition is a somewhat watered-down version (no exercises) of the Norwegian edition that from 1941 to 1969 was used by nearly 100,000 university students in the *examen philosophicum*. Its purpose, to quote the *Times Literary Supplement*, is " . . .to teach people in a democratic society to think clearly, coherently, and above all responsibly." Naess's hope is that teachers use controversial examples from current events—the more emotional the better—to confront students with their own confusion and encourage them to strive for higher levels of depth of intention. The final chapter outlines six "Gandhian" rules of effective discussion, which emphasize avoiding six forms of "irrelevance in discussion."

The first two volumes of selected papers (SWAN VIII and IX) contain important material that is not covered by the preceding volumes, material that complements them, or material that builds on or reevaluates positions taken earlier. Volume VIII includes sections on "Empirical Semantics and Truth," "Zeteticism," "Empiricism, Possibilism, and Pluralism," and "Metaphysics, Morals, and Gestalt Ontology." Volume IX includes sections on "Democracy, Ideology, and Rationality," "Philosophy of Science," "The Philosophy of Peace, Gandhian Ethics, and Communication," "Spinoza," and "Philosophical Development, Environment, and Education" (which includes an autobiographical article describing key influences in Naess's philosophical evolution, "How My Philosophy Seemed to Develop" and an interview, "Deep Ecology and Education"). A number of the especially significant articles have already been referred to, where relevant, in the discussion of Naess's philosophical evolution; other articles are discussed in the notes.

Today, Naess is, perhaps, best known for his "deep ecology" writings, the topic of *Deep Ecology of Wisdom* (SWAN X). This work began with a short unpublished paper written in 1965, "Nature ebbing out" (in SWAN X), and continues to this day. As the primary architect of deep ecology, Naess has

more than seventy-five published articles and book chapters and more than sixty unpublished pieces on this topic. His only book-length discussion of deep ecology began with a short mimeograph, *Økologi og Filosofi* (Ecology and philosophy), published in 1971. The fifth revision and expansion of this initial work resulted in the 1976 classic, *Økologi, Samfunn og Livsstil* (Ecology, community, and lifestyle), which has been translated into Swedish, English (1989), Italian, Japanese, and Czech. This book has not been included in the *Selected Works* because it is widely available and currently in print.

Volume X is the first comprehensive collection of Naess's work on deep ecology—it includes a broad array of articles on its history, influences, theory, development, practice, and prospects. This volume shows how deep ecology represents the integration and culmination of Naess's lifelong interests in philosophy, social research, activism, science, and nature. It demonstrates how Naess, in his explication and elaboration of deep ecology, draws extensively from both his life experience and his research on empirical semantics, scientific and cultural pluralism, Pyrrhonic scepticism, Spinozistic nondualism and activeness in relation to problems, gestalt ontology, normative systems theory, total views, and Gandhi's concepts of self-realization and nonviolent communication. Volume X also shows how Naess's approach to deep ecology has unfolded over time, with substantial emendation, in part as a response to the worsening ecological crisis, in part to answer criticisms that deep ecology was turning into a cult or religion, and in part to address the considerable confusion and controversy that arose from his use of provocative terminology and philosophical vagueness.

Ever since he coined the term *deep ecology* with his now famous paper "The shallow and the deep, long-range ecology movement: A summary," (in SWAN X) given at the 1972 Third World Future Conference in Bucharest, Naess's central concern has been to use philosophy and philosophical thinking to help humans overcome the ecological crisis and, ultimately, to restore the Earth to a state of rich and flourishing biological and cultural diversity (see volume X). A basic premise is that some ethical norms, particularly those grounded in spontaneous experience, can be tentatively accepted as objectively valid. An example for Naess would be the statement that "Every living being has an equal right to live and flourish, *in principle*." This statement in no way denies that maintaining our existence necessitates killing living beings. Another key premise is that the human potential for caring is not static or

SERIES EDITOR'S INTRODUCTION

limited—it can be both extended and deepened. The ecological crisis is embedded in an ecocultural crisis. Its resolution will necessitate cooperation and collaboration among the peace, social justice, and ecology movements.

Naess does not see himself as “inventing” deep ecology. Rather, he gave a name and a philosophical framework to a minority tradition, a nascent social movement that has been with humanity since at least Buddha, Chuang Tzu, Saint Francis of Assisi, Thoreau, John Muir, and Aldo Leopold, and is epitomized by Marjory Stoneman Douglas’s 1947 *Everglades: River of Grass* and subsequent crusade to save the Everglades.²⁹ This movement finally came of age in the contemporary era after Rachel Carson’s *Silent Spring*. Naess’s work on “deep ecology” can be subdivided into three main thematic areas.³⁰

What I refer to as Naess’s deep ecology approach (deep ecology as an ecophilosophical approach) represents his contributions to deep ecology theory—it is essentially an outline of a general philosophy of life, which draws considerable inspiration from Gandhi and Spinoza. The focal points are encouraging ultimate beliefs that support our capacity to identify with all living beings and Naess’s general, pluralistic, normative systems-based strategy for assisting individuals in the process of weaving their ultimate beliefs, descriptive and prescriptive premises about the world, ecological science, and philosophy into systematic conceptual structures for relating to the world—ecologically inspired *total views* or *ecosophies*.

His work characterizing and supporting deep ecology as an international, grassroots social and political movement, along with his work entering into the fray, addressing conflicts, implications, and practical applications of the theory, falls into the realm of contributions to the “deep ecology movement.” Supporters of the deep ecology movement are not united by a commitment to deep ecology as an academic ecophilosophy (which they may not be familiar with or embrace), but by their willingness to endorse the eight-point deep ecology platform, prepared by Naess and Sessions in 1984.³¹ Finally, work discussing his personal systematization of a deep ecological total view falls into the realm of “Ecosophy T.”

Naess coined the terms *deep ecology* and *shallow ecology* in 1972 to juxtapose what he regarded as two radically different approaches for problematizing (*Problematisieren*) and responding to the ecological crisis. In proposing the deep/shallow contrast, he made a technical semantic distinction directed at our level of problematizing—the extent to which we can, and do, coherently and consistently trace our views, practices, and actions back

to our ultimate beliefs or bedrock assumptions. Naess starts with a premise, which he has investigated empirically, that at the level of their ultimate beliefs, people generally identify with and appreciate nature. He then uses this to argue that many regrettable environmental decisions are made in a state of "philosophical stupor," in which narrow concerns are confused with, and then substituted for, more fundamental ones.

The "shallow," currently more influential approach to environmentalism is identified with treating the symptoms of the ecological crisis, such as pollution and resource degradation. This reform-oriented approach is grounded in technological optimism, economic growth, and scientific management, not in ultimate premises that plumb the relationship between people and nature. It thus ultimately fails to address the philosophical, social, and political roots of the ecocultural crisis.

The "deep" approach, on the other hand, while in no way discounting the exigency of addressing pollution and resource degradation, adopts a broader, long-term, more sceptical stance. Doubtful about technological optimism, critical of limitless economic growth, and decidedly against valuing nature in purely instrumental terms, it asks if the shallow approach's proposed solutions take into consideration the nature of reality and the complexity of the problems its adherents hope to rectify. Stressing the importance of addressing the fundamental roots and coevolving causes of the ecological crisis, deep ecology posits that along with humans' special capacities for reason and moral consciousness come special responsibilities, particularly in relation to the flourishing of nonhuman life and the ecocultural sustainability of the planet.

The deep ecology approach calls for expanding our sphere of concern to all living beings—charismatic or dull, gargantuan or tiny, sentient or not. It acknowledges that every living being has value in itself and views the flourishing of nature and culture as fundamentally intertwined—as part of one reality. This *wide-identification* is characterized by the perception that all life is interdependent; common goals bind all living beings to the life process. In Naess's view one can arrive at wide-identification by drawing on a broad diversity of philosophical or religious ultimate premises, with roots ranging from Christian Stewardship to the Gaia Hypothesis to Naess's own ontologically inspired "Self-realization!" In its most expansive form, wide-identification is the intuition that nature's interests and our own coincide, as with Naess's "Self-realization!"—something akin to a blending of the

SERIES EDITOR'S INTRODUCTION

Hindu *ātman* with a biospherical Pareto-optimality principle. Simply stated, this principle asserts that the increased realization of any individual or species rests on advancing (or at least not hindering) the realization potential of all other individuals or species.

By juxtaposing these two, almost caricatured perspectives, Naess employs a technique of Gandhian nonviolent communication designed to confront core disagreements. The central premise is that society's potential to overcome the ecological crisis rests on guiding discussion and debate to its root causes. One of the primary root causes, Naess asserts, is the widespread disjunction between people's core beliefs and their actions. People, in general, neither comprehend how their practices and everyday lifestyle choices harm the environment, nor recognize how these consequences may be in direct conflict with their core beliefs—this is the primary weakness of the shallow approach. A crucial, underlying hypothesis of the deep approach is that teasing out the presumed inconsistencies between an individual's actions and his or her fundamental beliefs, while possibly engendering serious ancillary conflict along the way, will ultimately generate progress toward ecocultural sustainability.

Naess contends, as I have pointed out earlier, that humans act as if we have total views whether or not we make such structures explicit. Because our decisions regarding society and nature are guided by our total views, Naess maintains, we *should* attempt to articulate them. By making these structures explicit, we expand both our opportunities for fruitful debate and interchange and our possibilities for creating policies that are consistent with our collective ultimate beliefs. This focus on praxis (responsibility and action) separates the deep ecology approach from more descriptive inquiries into environmental philosophy that focus on axiological questions, such as extending "rights" to certain nonhuman life-forms or grading intrinsic value. The ontologically inspired deep ecology approach attempts to counter the perception of fundamental people/environment and spiritual/physical cleavages. Its primary strategy for overcoming the ecological crisis is to help individuals avoid pseudo-rational thinking.

In relating this notion of persistently asking deeper questions to the ecological crisis, Naess broadens his concept of "depth." In the context of deep ecology as an ecophilosophical approach, depth refers to both the general level of problematizing we employ in seeking out the underlying, co-

evolving causes of the ecocultural crisis and the extent of our willingness to consider an expansive array of social and policy responses, even if they necessitate changes that constitute a radical departure from the status quo. Rather than calling for a new environmental ethic or a radical change in fundamental values, Naess's approach to ecophilosophy centers on transforming practice and policy by challenging us to develop more thoroughly reasoned, consistent, and ecologically inspired total views. This work represents a culmination of his effort to integrate reason and emotion. He has created the foundation for a new and promising human/nature relationship that positions humans as plain citizens with special abilities and unique responsibilities and nature as mentor, measure, and partner rather than servant. The current state of global ecological unsustainability has made Naess state that he is optimistic about the twenty-second century but pessimistic about the twenty-first; humans have a long way to go.

Deep ecology has been criticized for being too critical of pragmatic efforts to address acute environmental problems. It has also been accused of being inherently fascist, antihumanist, antifeminist, and against having indigenous peoples share wilderness areas with nonhuman life-forms.³² As the articles in volume X will show, none of these criticisms are compatible with a sophisticated reading of Naess's writings on deep ecology as an ecophilosophical approach. This is not to suggest that deep ecology as an ecophilosophical approach has clear answers. In inspiring many people to reconsider their value priorities and more consistently relate them to their lifestyles and everyday actions, deep ecology opens more questions than it answers. Three key issues for future research loom on the horizon. First, how can society motivate value priorities for ecological sustainability when individuals do not, on first principles, embrace wide-identification? Second, does taking a deep ecological perspective over a shallow ecological perspective actually result in better policy—policies that lead to long-term protection of cultural and biological diversity, using democratic, noncoercive, and ethically unobjectionable means? Third, how can deep ecology help resolve conflicts in environmental decision making when those conflicts result not from pseudorational thinking but from genuine value conflicts?

Throughout this essay, I have tried to show how Naess's life of rich and varied spontaneous experiences and internal tensions have shaped not only

SERIES EDITOR'S INTRODUCTION

who he is as a person, but also who he is as a philosopher. Viewed separately, Naess's contributions to academic philosophy, social research, and ecological philosophy and activism can appear discordant, dilettantish, and incoherent. When, through careful study of his helical progression, his philosophical and personal maturation, the pattern of the whole unexpectedly reveals itself as a unity, the whole suddenly becomes much more than the simple sum of individual books and articles. With the distance of a meta-perspective, Naess's collective philosophical contributions can be seen as a mosaic—as a superordinate gestalt, in some sense, as a rich and inspiring, but inevitably fragmentary total view. Naess has breathed life back into the study of philosophy by turning its study back to life. With his cultivation of a meta-perspective, a whole, new (old) approach to philosophy and way of seeing the world emerges. This richly patterned mosaic, by encouraging us to celebrate our freedom and affirm life, can help us to reshape our relationship to each other and the Earth in new and promising ways.

Conclusion

It was only as a professor that I became aware of the difficulties of suppressing the significance of the development of feelings in human affairs while at the same time worshipping reason. Both are constantly needed.

Arne Naess, *Life's Philosophy*

The ten volumes of this series (along with a subsequent volume of conversations between Naess and myself on deep ecology and his philosophy) make available for the first time access to the breadth and depth of Naess's philosophical thought. Efforts to judge the significance of Naess's philosophical oeuvre—assertions made in the first sentence of this essay—can now be taken up on an informed basis. When embarking on this process, it may prove beneficial to reflect on Henry Adams's insight on the fundamental limitations of communication, and especially the limits of communicating one's fragmentary total view, "No one means all he says, and yet very few say all they mean, for words are slippery and thought is viscous."³³ Spinoza ends the *Ethics* with the following remark: *Sed omnia praeclara tam difficilia, quam rara sunt* ("But all very clear things are as difficult as rare").

In *The Radical Spinoza*, Wienpahl translates the phrase more literally

than usual, rendering *praeclara* as “very clear” rather than the typical “excellent.”³⁴ The quest for clarity is painful and difficult as well as amaranthine. The alternative, however, is to abandon joy and freedom and thus meaning. This is the essence of Naess’s distinction between being an *academic philosopher* and being a *philosopher of life*, between merely *functioning* and *living*. Drawing inspiration from Spinoza, Naess has cultivated a practice of both integrating reason and emotion *and* transforming negative emotions into positive ones. His challenge is before us and the frontier is long—the choice, however, is ours.

Editorial Approach

Naess has always written books as if they were exercises for himself, tentative formulations that chronicled his views at that very second but were always subject to change. As I indicated previously, many of the prior editions of his books were poorly edited and sparsely documented. Existing bibliographies were incomplete, and indexes (in the rare cases in which they existed) were always inadequate. Quotations were often transcribed incorrectly and ill-referenced. In addition, the breadth of his work was enormous and sometimes repetitive. Arriving at a plan for a representative *Selected Works* that would have a consistent format and design was no easy task.

All the selections for the *Selected Works* were made in close consultation with Naess. I would prepare recommendations from my master bibliography file and then, whenever we disagreed, we would discuss the pros and cons of the piece and whether it was appropriate for inclusion (this approach proved particularly helpful when we reached the *Selected Papers* volumes). We immediately made a decision to exclude works that were widely available and currently in print. Other important works, such as his dissertation, and his major work on lay people’s conception of truth, his work on the semantics of democracy and ideological controversy, and his contributions to history of philosophy were more difficult to exclude, but the nature of the project as a selected works demanded such tough choices. I was encouraged by the fact that Naess often published articles that summarized or updated earlier works. In the end, I was able to reflect a significant portion of the ideas and concepts in these excluded works by including articles of that type in one of the three *Selected Papers* volumes.

SERIES EDITOR'S INTRODUCTION

The details of editing proved more complex. Much to my chagrin, I very humbly learned how much work goes into a project of this scale and complexity. We decided early on that the level of editing required to bring the prior publications up to the high standards of contemporary academic philosophical publishing would necessitate revised editions. We also decided that since we were preparing revised editions and Naess was alive and could review the work, we would make the role of the editor invisible and not include tedious footnotes chronicling all the changes, however significant they might be. The historical significance, intricacy, and sheer magnitude of *Interpretation and Preciseness* (SWAN I) warranted special consideration. For these reasons, we decided that it would be best to prepare only an edited version for this volume and not attempt a complete revision as with the other volumes. In the early stages of the project Naess and I worked together closely, intimately. In my effort to eliminate errors and to enhance readability, flow, and clarity of argument, I brought Naess question after tedious question when I first embarked on the project (particularly when I was in Norway as a Fulbright Scholar in 1996). After working through several manuscripts, Naess decided to place the remainder of the responsibility for revising and editing the manuscripts in my hands.

We have made our best effort to reconcile inconsistencies, make corrections, and chase down incomplete bibliographic references (in most cases no bibliographies existed for the original works). I regret, however, that some imperfections remain. I am also responsible for any new errors that have been introduced—their existence, unfortunately, is unavoidable. I am, however, heartened by a conversation I had with Naess midway through the project, after he had reviewed several drafts of revised manuscripts. He commented that at least 90 percent of my revisions resulted in improvement and that no significant misinterpretations had been introduced. Given the nature and complexity of this project, that sounded like odds I could live with.

Acknowledgments

A project of this magnitude, by its very nature, represents the labor and love of an entire community. It could never have gotten off the ground, much less been completed, without a fantastic and deeply committed team. I have been blessed by the opportunity to work with, learn from, and re-

SERIES EDITOR'S INTRODUCTION

ceive guidance and support from so many talented friends and colleagues. It's been a wild ride; I owe you all a tremendous debt of gratitude.

First, the inspiration for the *Selected Works* and the majority of its financial support are due to the foresight and generosity of "Miracle Doug," Douglas Tompkins, president of the Foundation for Deep Ecology (FDE). Thanks for your vision, Doug. Quincey Tompkins Imhoff, former executive director of the Foundation (and current vice president of the board), also deserves recognition for her tremendous support during the early years of the project, as do program directors Jerry Mander and John Davis. Special thanks also go to Sharon Donovan, the Foundation's publishing manager, who in the project's final years has guided it through a long and sometimes circuitous path to completion. The Foundation has also always had an amazingly gifted and dedicated staff. At one point or another, many of its staff had a hand in helping this project along—offering assistance at a key point, a kind word, inspiration, or simply good cheer and a smile. Thank you, Denise Wilson, Debi Barker, Esther Li, Lizzie Udwin, Julie Lindow, Miyo Sakashita, and Emily Lydgate.

I was also supported by the Fulbright Foundation with a senior research/teaching fellowship at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. Additional support came from Western Michigan University. Special thanks go to WMU's dean of the College of Arts and Sciences, Leonard Ginsberg, and to my chair, Thomas Bailey. My colleagues at Western Michigan University also deserve thanks for their tolerance and succor while I focused all my available energies on this project. I am grateful for their flexibility and generous support. Wil Emmert, one of WMU's Research and Program officers, also deserves a great thanks for his patience and skillful assistance.

The project has been blessed with a distinguished advisory board—Robert S. Cohen, Bill Devall, Alan Drengson, Ingemund Gullvåg (deceased), Per Ingvar Haukeland, Kit-Fai Naess, Nicolas Rescher, George Sessions, Michael Soulé, Douglas Tompkins, and Jon Wetleson. All of the advisers offered significant assistance in one form or another. Bob Cohen graciously shared his expertise and offered invaluable advice, encouragement, and support throughout the project. Bill Devall gave encouragement and helped bring volume X to completion by coauthoring its preface.

SERIES EDITOR'S INTRODUCTION

George Sessions offered advice on the selections for volume X, provided guidance, and carefully reviewed a draft of this introduction. His suggestions greatly improved its flow and clarity. Kit-Fai Naess's tremendous moral support and great assistance in locating obscure documents and preparing bibliographies were invaluable.

Alan Drengson's contribution as a project adviser and in the project's final year as Associate Editor deserves special mention. At a crucial time, when the project was stalled in its later stages, Alan stepped up to the plate and played a key role in helping shepherd the project to completion. In particular, he took over most of the day-to-day project-coordination responsibilities for the final year of the project. He reviewed the copyedited manuscripts for volumes I, VIII, IX, and X, oversaw preparation of the author's prefaces to each volume and the editors' prefaces to volumes VIII, IX, and X, and reviewed the final manuscript proofs. This was not an easy task. I owe Alan a great debt for his fortitude, commitment, and generosity. For his contribution to the difficult and taxing responsibility of overseeing the final preparation of volume I, he has been credited as its sole editor.

I am lucky to have been supported by two astonishingly capable, committed, and patient project assistants. Kim Zetter played a critical role in getting the project off the ground and keeping it on schedule for the first three years. Later, Barbara Pijan helped steer the project back on track and over some awkward obstacles after it had run off course. Their talent and dedication played a major role in bringing to life the books before you. Thank you, Kim and Barbara, for your stalwart devotion to the project.

The beautiful and elegant design of the series is the work of Tomatsu Yagi and his nephew Akira Yagi. Ralph Fowler played a significant role in executing the Yagis' design and by filling in any missing gaps. Ralph also performed the typesetting for volumes II–VII. The skillful and efficient crew at BookMatters performed the remainder of the typesetting. Katherine Silver handled the Brobdingnagian task of project management on volumes I and VIII–X and the last crucial stages of the project with aplomb, attention to detail, and fortitude.

The bulk of the project's copyediting was performed by the meticulous and supertalented Anne C. Collins, Ph.D., copyeditor extraordinaire. Additional copyediting was provided by Mary Anne Stewart and Kathy Walker. Indexing was performed by the immensely competent Nancy Mul-

SERIES EDITOR'S INTRODUCTION

vaney of Bayside Indexing Service, Julie Shawvan, and Leonard S. Rosenbaum. Proofreading was provided by Carrie Pickett.

Ingemund Gullvåg translated *Which World Is the Real One?* Iver Ørstavik provided the translation of "Experts' views on the inherent value of nature." The original editions of Naess's texts were keyed or scanned by the able and efficient crew at AgAccess—David Katz, Karen van Eppen, Jacob Katz, Rachna Boon, and Tim Rice. Additional keying of articles for the *Selected Papers* volumes was provided by Nancy Ropecka and Jane Drengson. Barbara Pijan, d Jones, Tony Hainault, and Debbie Reid deserve thanks for their careful and thorough transcribing of more than thirty-five hours of discussions with Arne Naess. Thanks are also owed to Tim Quick for his help with bibliographic research for volumes I and VIII–X, and to Kelly McKernan for assisting Alan with photocopying and faxing. In addition, a special thanks goes to Robert P. Goldman, Sarah Kailath Professor of Sanskrit and Indian Studies at the University of California Berkeley, for generously and graciously offering assistance on contemporary Sanskrit and Hindi terms.

I am grateful to the dedicated and very patient staff at Kluwer Academic Publishing. I am sad that our original editor, the immensely talented Annie Kuipers, who first recognized the importance of this project, did not live to see it come to print. Stephanie Harmon, Annie's replacement, worked closely with me on editorial matters and on finding high-quality recycled paper, cloth, foil, and other materials that meet the strict environmental considerations of FDE. In the final five years, the able and gifted Charles Erkelens was our editor.

Additional advice and moral support were provided by colleagues, friends, and family: Aimee Carroll, Kirsten Coyne, Paul Craig, Neal Goodwin, Byron Hahn, Ladislav Hanka, Alastair Hannay, Anna Leidberg-Miron, Danny Moses, Richard Norgaard, Max Oelschlaeger, Brian Recht, Stephanie Sarvar, Ed Saxon, Geir Michael Sommerhein, Petter Sorum, and Kristin Walstad. Thanks for your efforts to coax me out of the cave.

Special thanks go to d and Reuben for their forbearance and succor. Someday, all too soon, Reuben will recognize that the invisible "work fairies" that were constantly pulling me back to my office don't actually exist. I can't wait.

Most of all, thanks to Arne Naess for placing his trust in me—it's been

SERIES EDITOR'S INTRODUCTION

a gift, something like an extended trudge up to Tvergastein, but without the fresh air and perspective. Taking on this project has been somewhat like receiving Pandora's box as a present—all sorts of ills and plagues reared their heads along the way. I often felt that I was on a never-ending climbing descent in the night. I was always wondering about rappelling off my rope into the abyss.

The SWAN has taken flight, and I have landed on firm ground—I think? In all seriousness, I learned invaluable lessons. The more I worked through Arne's writings, the more open-minded and optimistic I became. I found myself cultivating perspective and looking at the problems and challenges before me with fresh insights. I also found myself responding with more grace and equanimity in my efforts to counteract the numbing effects of contemporary society.

It is strange and ironic, however, that in being the series editor for the *Selected Works* of the father of deep ecology I spent so much time inside, chained to a desk. But this is part of the paradox of working with Arne Naess. I am reminded of one of my favorite poems—Gary Snyder's "Axe Handles." The last few lines read:

Pound was an Axe,
Chen was an axe, I am an axe,
And my son a handle, soon
To be shaping again, model
And tool, craft of culture,
How we go on.

And then it makes sense.

Harold Glasser
2004

Notes

1. In writing this essay, I found myself drawing on more than twelve years of friendship with Arne Naess. A simple bibliography could not do justice to describing how this subtle and multilayered gestalt has been formed. My perception of Naess and his work has been shaped by more than thirty-five

SERIES EDITOR'S INTRODUCTION

hours of transcribed conversations between us, countless other conversations, letters, scraps of paper, e-mails, and Arne's copious annotations in my own books and articles. Camping trips, bouldering, hikes, and cross-country skis have also helped inform my understanding of Arne Naess the fiercely competitive, playful, elfin trickster, who springs to life in nature. I have benefited from three extended visits to Norway, including a Senior Fulbright at the University of Oslo's Centre for Development and the Environment and Institute of Philosophy in 1996. I have also spent other stimulating periods of time with Arne in Svalbaard, England, California, and the deserts of Arizona and Nevada. Finally, and probably most important, I have been inspired and forever changed by my own reading and editing of his work. In this regard, both previously published and unpublished materials have been influential in forming my own perspective on Arne Naess the philosopher. One key published source has been Naess's "How my philosophy seemed to develop," in *Philosophers on Their Own Work*, edited by Andre Mercier and Maja Svilar (Bern: Peter Lang, 1983), pp. 209–26 (in SWAN IX). Another source for insightful material on Naess and A. J. Ayer (as well as six of their contemporaries) is a book created from debates by philosophers for Dutch National Television. See, especially, "The glass is on the table: An empiricist versus a total view," in *Reflexive Water: The Basic Concerns of Mankind*, edited by Fons Elders (London: Souvenir Press, 1974), pp. 11–68 (in SWAN VIII). Finally, additional perspective was offered by an article that discusses Norwegian philosophy from the end of the Second World War to just before 1980: Arne Naess and Jon Hellesnes, "Norway," in *Handbook of World Philosophy Since 1945*, edited by John Burr (Westport, CT: Greenwood Press, 1980), pp. 159–71.

On some of the fine points of this essay, I have benefited from extended conversations with my colleague and old friend George Sessions. I have also profited, over the years, from the significant literature that has been created to shed light on Arne's life and work. Many of the ideas and thoughts introduced in this essay—drawn from my own firsthand experiences with Arne—can also be found in these sources. In many cases, issues only touched on here are taken up in much more detail in those sources. Five key references for historical material on Naess and the evolution of his philosophical approach are identified below (two of which are videos). A wealth of additional material is available in the five festschrifts for Naess (see details in note 15 below). The first of the festschrifts, *In Sceptical Wonder: Inquiries into the Philosophy of Arne Naess on the Occasion of His Seventieth Birthday*, edited by Ingemund Gullvåg and Jon Wetlesen (Oslo: Universitetsforlaget, 1982), contains the most thoroughgoing analyses and critiques of Naess's earlier philosophy that I am aware of, and many of the articles have insightful responses by Naess.

Singh, ed., *Environmental Ethics and the Power of Place: Festschrift to Arne Naess* (Varanasi, India: National Geographical Journal of India, 1994); Nina Witoszek and Andrew Brennan, eds., *Philosophical Dialogues: Arne Naess and the Progress of Ecophilosophy* (Oslo: Centre for Development and the Environment, 1997; Lanham, MD: Roman and Littlefield, 1998); Andrew Light and David Rothenberg, eds., *Arne Naess's Environmental Thought*, special edition of *Inquiry* 39 (June 1996).
16. Arne Naess, *Four Modern Philosophers: Carnap, Wittgenstein, Heidegger, Sartre*, translated by Alastair Hannay (Chicago: University of Chicago Press, 1968). In the 1970s, philosophy was still influenced by the events of the Second World War. Heidegger's flirtation with National Socialism and the Hitler regime, and his unusual way of expressing himself, made it difficult for him to be considered a great philosopher. Naess's book on four contemporary philosophers was seen as unique because he interpreted in a scholarly and positive way both Heidegger and the fiercely anti-Heideggerian philosopher

SERIES EDITOR'S INTRODUCTION

Rudolph Carnap, a logical empiricist. Carnap, who was forced to flee Nazi Germany, could not fathom how Naess, as an old friend, could present positive discussions of Heidegger and himself in the same book. The other two philosophers included in the book, Wittgenstein and Sartre, also held completely incompatible views of philosophy, but Naess accorded them equally high positive appreciation.

17. For example, works by Naess that are still in print, such as *Ecology, Community, and Lifestyle: Outline of an Ecosophy*, translated and edited by David Rothenberg (Cambridge: The University Press, 1989), and *Life's Philosophy* (2002; see note 2), were not included, for obvious reasons.
18. In "How my philosophy seemed to develop," p. 215, Naess mentions the particularly strong impression, the magnificent expansion of his own "life's frame of reference," made by H. G. Wells's early popularization of the history of life, *Outline of History* (New York: Macmillan, 1920).
19. For detailed discussions of Naess's assessment of logical empiricism, see Arne Naess, "How can the empirical movement be promoted today? A discussion of the empiricism of Otto Neurath and Rudolph Carnap," in *From an Empirical Point of View: The Empirical Turn in Logic*, edited by E. M. Barth, J. Vandormael, and F. Vandamme (Gent, Belgium: Communication and Cognition, 1992), pp. 107–55 (in SWAN VIII). (The original German version of Naess's article, "Wie Fördert Man Heute die Empirische Bewegung? Eine Auseinandersetzung mit dem Empirismus von Otto Neurath und Rudolph Carnap," was written during 1937–39.) For Naess's experiences attending the Schlick seminar, see Arne Naess, "Logical empiricism and the uniqueness of the Schlick seminar: A personal experience with consequences," in *Scientific Philosophy*, edited by Friedrich Stadler (Dordrecht: Kluwer Academic, 1993), pp. 11–25 (in SWAN VIII).
20. Naess, "How my philosophy seemed to develop," p. 222.

Schilpp (Chicago: Northwestern University Press, 1939), p. 597, as quoted in Wallace I. Matson, *A New History of Philosophy*, vol. 2 (San Diego: Harcourt Brace Jovanovich, 1987), p. 454.
23. Naess, "How my philosophy seemed to develop," p. 223. For more details, see Richard McKeon and Stein Rokkan, eds., *Democracy in a World of Tensions* (Chicago: University of Chicago Press, 1951). Naess, as the scientific leader of the project, was viewed as a UNESCO administrator; he was only credited as being the author of the questionnaire itself and the summary paper, although he was intimately involved with the project at all levels.

SERIES EDITOR'S INTRODUCTION

24. Naess went on to perform a reconnaissance of Tirich Mir (25,263 feet) in the Hindu Kush in the summer of 1949. He then led the successful Norwegian first-ascent team in 1950. The expedition, which included botanical and geological assessments of the region, is chronicled by the team members in Naess et al., *Tirich Mir: The Norwegian Himalaya Expedition*, translated by Sölvi and Richard Bateson (London: Hodder and Stoughton, 1952). Naess successfully pursued a second, vastly more technical expedition to Tirich Mir in 1964. His "The south wall of Tirich Mir East," *Himalayan Journal* 26 (1965): 97–106, discusses this expedition and includes interesting commentary on expedition philosophy and climbing ethics. The article appears in SWAN X, along with other papers on Naess's relationship to mountains and views on mountaineering.

31. For anthologies on the deep ecology movement, which include articles by Naess and other deep ecology supporters, see George Sessions, ed., *Deep Ecology for the Twenty-First Century* (Boston: Shambhala, 1995), and Alan Drengson and Yuichi Inoue, eds., *The Deep Ecology Movement: An Introductory Anthology* (Berkeley, CA: North Atlantic Books, 1995).
32. Naess rarely responds directly and definitively to these criticisms—this is not his nature. Siri Naess, however, made an interesting effort to explore the potential of using Naess's Ecosophy T as an inspiration for a feminist normative system in her "Self-realization," in *In Sceptical Wonder*, pp. 270–81. She concluded that while Ecosophy T and her System F have much in common, Ecosophy T goes further by extending to all living beings its concern for activeness and creativity in relation to problems, egalitarianism, and support of the suppressed and exploited.

Author's Introduction to the Series

At ninety-two it is a great honor to be still alive and to witness the publication of my selected works in English. Few philosophers have their work published in a series, fewer still receive this honor before they die. When I was originally approached with the idea of publishing my complete works, I was overwhelmed and overjoyed, but added that not all my books and articles were important enough to merit such an honor. Selected works? Yes, and I am extremely grateful for this initiative and the final result, which presents a representative selection of my work from the earliest to the most recent. [*The Selected Works of Arne Naess* are hereafter referred to as SWAN.]

My interest in philosophy began with Spinoza's *Ethics*, which as a seventeen-year-old I was fortunate to read in Latin. I appreciated Spinoza's grand vision and trusted him implicitly as a person. I accepted that human beings could, and should, have a general outlook with the grandeur of Spinoza's, but I recognized that our individual views on this grand scale will not be identical. Through the years I have realized that there is a splendid variety of interpretations of Spinoza (SWAN VI and IX). His texts are exceptionally rich. As the years have gone on, I have focused on how he leads us to realize we can increase our freedom and sense of connection with the world through strengthening and intensifying our *positive* emotions. For example, loving and caring for our place and others leads to an expansive sense of being part of a much larger world. Emphasizing hatred and anger, on the other hand, makes us feel smaller and isolated from the world. Spinoza, as I interpret him, would express this by saying that "We are as large as our love." Increasing our freedom as human beings leads us toward life in communities colored by friendship, sharing joy and sorrow.

Before I left gymnasium [the end of secondary education] the headmaster asked me, "What do you intend to be?" My immediate answer was

AUTHOR'S INTRODUCTION TO THE SERIES

"A philosopher." In fact, I had already conceived of myself as one. I viewed the writings of many contemporary philosophers that I was familiar with, however, as vague and airy and certainly not as inspiring as Spinoza.

My doctoral thesis in philosophy of science was an effort to remind us that in science the content of a theory is not independent of research behavior—the activities of observing, confirming, disconfirming, and so on, and that these are set within a deep context of place, history, and culture. Later, as a postdoctoral researcher at the University of California at Berkeley, I studied the behavior of experimental psychologists doing animal research.

In 1934 and 1935 I studied in Vienna and while there became a member of the famous Schlick seminar, the main discussion group of the Vienna Circle. Their quest for clarity and cordial cooperation in pursuit of knowledge led me to appreciate that "What do I mean?" is an open question. I concluded that we never intend to express anything extremely definite, even in mathematics or symbolic logic. I saw the importance of using empirical methods to find out how we actually use certain expressions and sentences. I developed and applied a wide variety of such methods, which became part of the core for the empirical semantics that runs through my work. I continued to do this type of research into the 1990s, my last project being one in which I questioned experts and policy makers about their ideas of values intrinsic to the natural world (in SWAN X).

In one of my earlier studies, I reviewed about 700 articles from philosophers concerning their use of the word *truth*. For the most part, I found these unconvincing and soon started on empirical studies of the use of *truth* among ordinary nonprofessional people and schoolchildren (in SWAN VIII). Many philosophers seemed to assume that ordinary people hold very naive views about these deep matters. I found through research that, on the contrary, the views articulated by these "ordinary" people were every bit as sophisticated as those held by professional philosophers. This reinforced my conviction that, generally, we greatly underestimate ourselves. Much academic philosophy was narrowly focused and abstract. Philosophers who elicited interest in wide-ranging issues of practical and global importance, such as nonviolence and social justice, have in my lifetime said things that were considered creative, but often too far out. In spite of consistent proclamations that science neither would nor could take over all the problems

AUTHOR'S INTRODUCTION TO THE SERIES

discussed by philosophers, I tried to argue in ways that reminded readers of science done as open inquiry, and I tried to emphasize that it is occasionally necessary to perform empirical research to illuminate or support a philosophical viewpoint.

My empirical and historical research led me to realize that there are no certainties and that there is a great diversity in our spontaneous experience as well as endless ways to describe and appreciate the complexities and values of the world. Thus, I realized that I am one of those lifetime seekers that the ancient Greeks called a *zetetic* (see SWAN II and VIII). From my research on scepticism and the foundations of science and logic, it became clear to me that pluralism (every event has many descriptions and possible outcomes), possibilism (anything can happen), and a healthy scepticism (always seeking the truth but never claiming it) make up the most consistent approach to respecting the perspectives and experiences of others, human and nonhuman.

From my empirical studies of semantics, and from my knowledge of several languages, I came to appreciate the complexity of communication. Being committed to Gandhian nonviolent communication, I saw the importance of avoiding dogmatism and fanaticism. One of the most important discoveries coming from this research, leading to the publication of my major book, *Interpretation and Preciseness* (SWAN I), was the insight that we cannot avoid values in any field of endeavor or research. There are no value-free inquiries or theories. Even if we refuse to express our values, this is itself an expression and choice of values. We must, therefore, be clear about our value choices and try to make them explicit. The choices we make, as Spinoza pointed out, shape the quality of our lives, and values emphasizing positive emotions or feelings are expansive and lead to our growth. We must become ever more aware of our choices and the values involved. Even pure logic assumes certain norms. Empirical research can shed light on these matters. My colleagues in philosophy often found my empirical work perplexing. I, in turn, grew to underrate the necessity of visiting great centers of philosophy, as I preferred to be close to or in the mountains.

When I visited the United States, it was mostly to climb in the mountains or walk and camp in the desert. On one fortunate visit, I dropped in at the graduate students' discussion room at Harvard. Speaking with students who were writing their doctoral theses in philosophy, I understood that my

AUTHOR'S INTRODUCTION TO THE SERIES

knowledge of contemporary philosophy, and of recent important contributions in its various fields, was narrowly limited to special themes of lively personal interest. Even in later years, the tendency to take personal inclination very seriously colored my contribution to the philosophical literature. As can be seen, though, from the titles in these *Selected Works*, my strongly felt interests span a rich variety of fields, philosophical traditions, and movements.

Since childhood I have experienced an intense joy in being together with animals and plants and in contemplating the immense evolutionary development of life on earth over millions of years. From an early age I also developed an intense love for mountains and for being in them. Much of my creative philosophical work was done at Tvergastein, my mountain hut in Norway (see SWAN X). My devotion to outdoor life is in the Norwegian tradition called *friluftsliv* (literally, free-air-life). In many respects, I approached philosophical and cross-cultural studies as if I were a field ecologist or naturalist. It was against this background that my work from the 1960s onward focused with close attention on cultural diversity, biodiversity, sustainability, and the deep ecology movement.

My work since the Second World War has been increasingly within movements such as those furthering social justice, peace, and ecological responsibility. During the war, I engaged in anti-Nazi activism, and from that time also in promilitant Gandhianism, a nonviolence that is not pacifist in the usual sense but insists that if it is a bloody fight for justice against injustice, we seek "the center of the conflict" and, if necessary, cooperate with people who use arms. During the Cold War, I participated in the "third side," against both communism and extreme anticommunism, for example, as the scientific leader of a UNESCO project bringing Marxist and anti-Marxist politicians and political science researchers together in an unbiased discussion of the essence of democracy and freedom. Some of the relevant publications are included in SWAN IX.

The broad spectrum of books and articles included in the *Selected Works* represents, in many ways, a chronicle of my passions and influences. The *Selected Works* record, albeit in an inevitably fragmentary way, one possible expression of these. My dream and hope is that some readers will be inspired by their sheer variety, and that young philosophers will be encouraged to let strong personal motivations steer their studies.

AUTHOR'S INTRODUCTION TO THE SERIES

Working habits vary. Some people write an article and go on to the next without looking back on the old one; others come back from time to time, radically revising and changing the old one. The latter is my way of working. Lecturing in many places about these subjects, I have found it natural to revise the old manuscripts until sometimes very little is left of the original. Therefore, I have always viewed my writing as preliminary; a year, five years, ten years after publication of the first editions I have itched to revise, *thoroughly* revise them. When my first book was printed in 1936, I went to watch the hulking presses printing out one page at a time. I was terrified, thinking of mistakes or some awkward sentences being duplicated again and again.

When I was offered the opportunity to have a selected-works series published, I immediately thought I would like to review all my work and ask how, from today's perspective, I might answer the difficult questions I had earlier attempted to probe. Such a task would have been a particularly difficult proposition, because although many of my books and articles contain new ideas, the ideas are often not developed as well as I might have hoped. But alas, I am saved—at my age there is not time for me to accomplish such a comprehensive reevaluation of my work; I do not even have the capacity to do it now in any case.

Who could contemplate undertaking a publishing project of such ambitious proportions? Douglas Tompkins, mountaineer, entrepreneur, protector of wilderness in Chile and Argentina, and creator of the Foundation for Deep Ecology, is such a person. "Miracle Doug," as I call him, likes the idea that the deep ecology slogans and the deep ecology approach were introduced by a philosopher. I am grateful to him for his firm conviction, inspiration, and great generosity. My gratitude, however, extends well beyond my thanks to Doug, to others who have supported and championed this project.

Quincey Imhoff, when executive director of the Foundation for Deep Ecology, supported SWAN with generous grants and other contributions. SWAN has also benefited from faithful assistance and cooperation in the preparation and editing of the manuscripts. The late Professor Ingemund Gullvåg prepared the initial translation of *Which World Is the Real One?* (SWAN III). Professor Alastair Hannay translated the first edition of *Communication and Argument* (SWAN VII) and offered invaluable suggestions

AUTHOR'S INTRODUCTION TO THE SERIES

for improving the readability of the first editions of *Scepticism* (SWAN II), *The Pluralist and Possibilist Aspect of the Scientific Enterprise* (SWAN IV), and *Gandhi and Group Conflict* (SWAN V).

Most of all, however, I am grateful to Harold Glasser, the series editor, and his assistant, Kim Zetter, who oversaw all aspects of the project from design to production. Glasser's unique combination of intellectual tenacity, attention to detail, mastery of my work, and cooperative spirit made him a natural to take on the monumental task of selecting and editing my works. Glasser not only labored to improve the English and clarity of each manuscript, but his keen ability to ferret out countless technical and pedagogical errors has resulted in substantial new editions of volumes II–VII that are both far more comprehensible and accessible than the originals. I thank him for his valiant work on this project, both during his stay in Norway as a visiting Fulbright professor, where we collaborated on a strategy for revising the previously existing material, and in the subsequent years it has taken to complete the project.

From the beginning of the SWAN Project in 1994, Alan Drengson has encouraged and helped to move this work forward in numerous ways. Especially in the last crucial stages of completing volumes I, VIII, IX, and X, his help and editorial oversight have been invaluable. Thanks for his devotion, good humor, and positive enthusiasm. Thanks to both Drengson and Tim Quick for their extensive bibliographic research. Thanks to Bill Devall for his support and encouragement and especially his help on the completion of volume X, *Deep Ecology of Wisdom*. Thanks to Anne Collins for her outstanding work as the copyeditor of the SWAN volumes. Thanks to George Sessions for his support and encouragement.

Last, but certainly not least, immeasurable thanks go to my wife, Kit-Fai Naess, who has worked beside me throughout the years to provide invaluable assistance, encouragement, and inspiration.

Arne Naess

2004

Preface

by Bill Devall and Alan Drengson

Arne Naess is a mountaineer, activist, teacher, scholar, philosopher, and national hero in his native Norway. When he attended the famous Vienna Circle discussions during the 1930s, he was impressed by the compassion and assistance that members of the circle gave to one another. During that time he also began studying Gandhi's nonviolent direct action campaigns in India. He later wrote a book (SWAN V) articulating Gandhi's norms of nonviolent direct action.

Born and raised in Norway, where outdoor life, or *friluftsliv*, is part of the national culture, Naess began climbing as a child. As a young man he built a hut high in the mountains, a place he calls Tvergastein. At Tvergastein and at the University of Oslo, he explored the history of Western and Eastern philosophy and also the history, biology, and geology of Mount Hallingskarvet, where his hut is located. At seventeen he started reading Spinoza's *Ethics*. He found in Spinoza's work an inspiring account of emotions that he has explored in his writings and personal experience. His own life's philosophy is called Ecosophy T, as it was born in the mountains at Tvergastein. Naess coined the word *ecosophy* from the ancient Greek words *ecos* for household place and *sophia* for wisdom. An ecosophy is a personal philosophy of life aiming for ecological wisdom and harmony.

The articles in this anthology were written during the decades from the 1960s through 2000. They represent Naess's evolving reflections on the deep ecology movement, diverse ecosophies, and ecophilosophy. He was the first to use the words *deep ecology movement* to refer to the international grassroots ecology movement that is united by a number of platform principles he calls the Eight Points. The first two principles emphasize the intrinsic value of all beings and of richness and diversity in life-forms and

cultures. Some of his main works in semantics, logic, philosophy of science, comparative philosophy, Gandhi, and Spinoza are found in other volumes of the SWAN series.

The theoretical and philosophical underpinnings of Naess's approach to deep ecology are found in this volume in section 7, "Understanding Naess's Unique Approach to Deep Ecology," and section 8, "Theoretical Dimensions of Deep Ecology and Ecosophy T." Readers who are particularly interested in the technical philosophical aspects of his ecophilosophy approach can read those sections before reading his work relevant to public policy issues and lifestyles, which are earlier in the volume, sections 2 and 3. Readers who want to understand his approach to the deep, long-range ecology movement could begin by looking at the "apron diagram" and his explanation of it in section 1, "The Long-Range Deep Ecology Movement."

The broad and representative selection of Naess's articles in this anthology should dispel some of the misconceptions about ecophilosophy and the deep, long-range ecology movement. We hope that new generations of readers, scholars, and ordinary people will appreciate the range and depth of his work. Throughout his career he has advocated what he calls "radical pluralism" and argued that philosophy is not restricted to academically trained philosophers. People in all walks of life, holding vastly different "ultimate norms," that is, different religious and philosophical positions, should develop their own ecosophy and total view. They can apply principles of the deep ecology platform to their lifestyle, politics, social policies, and community. They can better articulate their "sense of wonder" for nature and what they can do to lessen their own impacts on their place and the world.

Naess turned his attention to environmental issues and ecophilosophy during the 1960s. He read books by Rachel Carson, and her sense of wonder for nature inspired him to work on shifting to quality of life values and a nature-oriented sensibility that finds joy in the world of diverse beings. Carson's sense for the interconnected nature of the world and her scientific evaluation of the negative effects of massive herbicide and pesticide use are described in her book *Silent Spring* (1962). This turned him to thinking about the accelerating negative impacts on nature by contemporary industrial civilization and larger issues of ultimate aims and norms.

His first foray into ecophilosophy was in 1965 when he wrote a short

essay, "Nature ebbing out," published here for the first time. In the United States, the first Earth Day in 1970 was a historical landmark of the widespread concern over the accelerating destruction of nature by the forces of industrial society, rapid human population growth, and the rampant destruction of habitat for native species.

He presented his well-known seminal paper "The shallow and the deep, long-range ecology movement: A summary" in 1972 at an Eastern European conference on the future of research. In this paper, he describes the "shallow ecology movement" as an instrumental valuing of nature. It involves the "Fight against pollution and resource depletion. Central objective: the health and affluence of people in the developed nations." He said that this mainstream view is not a deep questioning approach. It assumes that we can go on with business as usual without deeply examining and changing our values and ultimate purposes. He describes the "deep ecology movement" as involving the recognition that we have to examine our basic relationships, values, and priorities with respect for each other and the natural world. Living beings are good for their own sake and have intrinsic value. This deep questioning approach leads us to see how our values, whether explicit or assumed, engender lifestyles that fail to honor our ecological responsibilities and the need for fundamental changes in industrial society. Ecologically based approaches involve "Rejection of the man-in-environment image in favor of the relational, total-field image." We are part of the larger ecological context and cannot stand outside it. We participate in it and affect it no matter what we do. It supports and affects us.

Some critics felt that the "shallow" and "deep" terminology was inappropriate. Naess replied that he was pointing to our usual "shallow" way of thinking and comparing it to a deeper questioning that could yield surprising insights and different, more creative ways of thinking, acting, and being in the world.

Section 1 of this anthology includes articles reflecting his emerging and changing articulation of what he calls the "basic intuitions of the deep ecology movement." These articles in this book span four decades from the 1960s through the 1990s. They expand on themes that Naess considers central to the deep, long-range ecology movement. He consistently uses the term *movement* when he discusses deep ecology. As an activist for peace, social justice, and ecological responsibility, he was deeply influenced by

Gandhi's work on nonviolent, direct grassroots action. He continues to say that the vast majority of supporters of the deep ecology movement, whether they use the phrase "deep ecology" or not, share an "intuition" that everything hangs together, and they feel a broader identification with nature. They seek to develop their own ecosophy or lifestyle to realize ecological wisdom. Naess is a long-term advocate for the peace and social justice movements. He points out that both of these movements should cooperate with the ecology movement. For the health of the planet and the health of human beings, an overriding norm should be "Ecological sustainability!"

Naess says that the deep ecology movement is one of the three great international grassroots movements of the twentieth century; the other two are the peace and social justice movements. He says that while these movements should cooperate with each other, the ecology movement has a special responsibility for conversations with and conservation of nature. The relationship between what he calls "ultimate premises," "the platform of the deep ecology movement," and specific coalitions for social change can be encouraged between greens, social justice advocates, and the peace movement, as briefly described in the article on the "apron diagram." In that explanation, he makes clear that his study of the international ecology movement is connected to a larger appreciation for grassroots movements. He distinguishes between four levels of discourse when discussing these issues.

The level of everyday life assumes certain values in our ordinary practices. When we begin to seek deeper clarification of our ultimate values, we are involved in deep questioning that leads us to state our ultimate norms and views about the nature of the world. The three great international grassroots movements each have a number of principles of a general nature that serve as a uniting ground, even though these movements are supported by people from different nations, cultures, and religions who hold different ultimate philosophies. The platform principles of the deep ecology movement proposed by Naess are stated in section 1 of this book. The four levels of discourse he describes are: ultimate philosophies, platform principles, policy formulations, and practical actions. There is great diversity at the level of ultimate philosophies but some unity at the level of platform principles. In the three great movements referred to above, there are platform principles that serve to unite people at the global level, although they have different personal philosophies and cultures. Policy and practical

action are also more diverse since they are adapted to specific cultures, places, and individuals. Naess says that the ecology movement is enriched by this wonderful cultural diversity and that it is unwise to try to have only one ultimate philosophy or religion in the world. Instead, his vision is of a great diversity of cultures and ecosophies. Followers of the deep ecology movement are inspired to work together locally and globally to move our societies and personal lives toward sustainability. Naess is a celebrant of individual and cultural diversity, believing that this is nature's way and that these are all interdependent with ecological diversity.

Naess continually encourages people to consider their own way of living in the world, both in politics and in daily life (sections 2 and 3). As a scholar of Spinoza, he urges us to consider the relevance to our personal lives of Spinoza's philosophy of feelings. By focusing on positive emotions, we increase our freedom and sense of belonging to a larger world. While many other writers evoke despair and hopelessness in our contemporary situation, Naess emphasizes various forms of joy. We can find joy in watching small birds, walking among wildflowers, enjoying companionship with friends, family, and nature. In the face of continuing, daily assaults on wild places, he advises us to have "a sense of joy in a world of fact" to keep our balance and inspiration. One of his favorite slogans is "The front is very long." There is a place in the deep, long-range ecology movement for all people who share the desire to dwell responsibly in this world. People can contribute to the well-being of other human beings and of nature in a wide variety of ways, including doing beautiful actions. His article "Beautiful Action: Its Function in the Ecological Crisis" (chapter 16) reflects his appreciation for the intrinsic value of certain types of action.

Naess has many sources of joy based on the Norwegian tradition of "free-air-life" (*friluftsliv*), which developed more than a century ago in Scandinavia as a social movement to spend more time outdoors through skiing, mountaineering, orienteering, and other forms of intimate contact with the natural world. His ecophilosophy is grounded in outdoor living and activities, empirical studies, and philosophical reflections.

As a mountaineer, Naess has been inspired by the mountains to write some of his most insightful and deep articles in ecophilosophy. He leads us to see how we can feel that mountains are sentient beings, and in stories they are also metaphors and mythic places, where he learned deep lessons

encouraging articulation of his own Ecosophy T. As already mentioned, the *T* is shorthand for Tvergastein, the mountain hut at which he wrote many of his books and articles. His use of mountains to illustrate lessons in deep-ecology living in balance is reflected in section 5, "The Significance of Place: At Home in the Mountains" and in other articles published elsewhere. His use of mountains in personal myth and as metaphors is reflected in this anthology in such articles as "Metaphysics of the Treeline," "Modesty and the Conquest of Mountains," "Some Ethical Considerations with a View to Mountaineering in Norway," and "The South Wall of Tirich Mir East."

Naess's work in ecophilosophy is connected to his broader reflections on "total systems." This book includes a selection of his reflections on "ultimate premises" and his methodology of "radical pluralism." These articles are essential to understanding the approach he takes to ecophilosophy. Articles in section 7 express his approach to and use of ontology and normative systems and include "Reflections about Total Views," "Notes on the Methodology of Normative Systems," and "The World of Concrete Contents."

Consistent with his emphasis that his approach to deep ecology is not restricted to academic philosophers, Naess has written articles on resolving social conflicts between human beings and wild animals such as whales, bears, and wolves. He emphasizes "nonviolent, direct action" based on Gandhi's ethics of conflict resolution. Examples of these articles in section 4 are "Self-Realization in Mixed Communities of Human Beings, Bears, Sheep, and Wolves," "The Tragedy of Norwegian Whaling," and "Philosophy of Wolf Policies I: General Principles and Preliminary Exploration of Selected Norms."

Naess has consistently encouraged supporters of the deep, long-range ecology movement to reflect on contemporary subjects of lifestyle, population growth, and sustainability of human communities. Articles on these issues include "Deep Ecology and Lifestyle," "Cultural Diversity and the Deep Ecology Movement," "Sustainable Development and Deep Ecology," and "Migration and Ecological Unsustainability." In contrast to some writers, he stresses that wildness and protection of wild places, some of which are inhabited by indigenous peoples, are essential for wise policies in all nations. He appreciates the wisdom in the lifestyles of many indigenous peoples as consistent with the platform principles of the deep ecology movement.

PREFACE BY BILL DEVAL AND ALAN DRENGSON

This anthology concludes with section 9, "Deep Ecology and the Future," which includes some of his reflections on issues for the twenty-first century and beyond. He believes the problems are huge, but so is human resourcefulness. He encourages us to live richly by appreciating the diversity of cultures and beings in this world we all share. He says that we should seek rich experiences using simple means, and take joy in simple pleasures. We can have a very rich life with low consumption of material things.

This volume concludes with a selected bibliography of Naess's works in English. It provides source material for scholars who want to pursue research into the development and formulation of Naess's lifework.

At ninety-two Naess continues to practice nonviolent direct action. He has done so throughout his long and distinguished career as a philosopher, activist, and articulator of deep ecological and social values. He also enjoys Gandhian tennis and boxing.

We hope that readers gain intellectual understanding of deep ecology through the articles in this anthology. We hope they will be inspired to articulate and live their own ecosophies, personal lifestyles committed to nonviolence, harmony with nature, and living fully and joyfully in the world. Let us go beyond what is merely required to act in beautiful and generous ways, giving gifts back to Gaia and our home places.

Bill Devall and Alan Drengson

2004

Author's Preface

Reflections on My Papers and the Selections in SWAN VIII–X

During my active life as a researcher and author, I have published far too much to be a polished writer. I have a long practice of working a set number of hours each day, and at ninety-two I have lived a long life. I hold to this even when I live in my mountain hut, Tvergastein. Over the years I have carried in many precious big reference books to put in its “library.” Writing philosophy in the hut, while looking over a vast mountain and alpine landscape, gave me a different feeling and perspective than when working in my office at the university or in my study at home. Each setting is very different and seems to bring out different aspects of the same subject and of myself. There are also the differences in dialect and local customs that fed my search for an ever more complete total view. To me this diversity is good to appreciate for its own sake. Writing, like teaching, is a way to find out things rather than just a dull report on the past. Writing philosophy for me is an ongoing project, a kind of meditation; in a sense, it is something that I must continue daily, because I continue to have more and more gestalts integrated into my total view with feelings of wholeness.

I never regarded the papers or even the books I wrote to be final drafts, but always works in progress, since my life, philosophy, and worldview are all in an ongoing process of change. Altogether, I have probably written thirty or so books published in various languages, and some in several languages. I have had many coauthoring adventures. There are manuscripts of books started but still in progress. I probably have some finished but unpublished book manuscripts. In the area of smaller-scale publications and writings, there are many kinds of pieces from very short to very long—for example, short reviews, long reviews, discussions, definitional pieces, long

AUTHOR'S PREFACE

single-subject essays, historically oriented papers, formal logic pieces, empirical studies, studies of conceptual systems—pieces on so many different subjects that I am somewhat embarrassed by my lack of attention to other things. I almost always write with passion but am not so keen to keep detailed records of my scholarly research, and at Tvergastein these resources are limited.

I have hundreds of manuscripts of articles, reviews, and other nonfiction pieces in my collection. The SWAN project has been a wonderful undertaking because it helped me to get my works organized to be more accessible to a larger audience. My dear wife, Kit-Fai, has been so good to my work that I can only describe her acts as beautiful. She, along with Harold Glasser, Alan Drengson, and others, plied me with endless questions about my works and individual pieces, for references, for greater clarity, for a better organization in time, and so on. The result is an assemblage of more than seven hundred published and unpublished papers.

We were choosing books to publish and papers for the anthologies of my selected works in English. We settled on seven books to be republished as the first seven volumes in the SWAN series. After some discussion with others, we decided to have three volumes of my papers for a total of ten volumes. We pondered what to include in the anthologies of papers and how to organize them. The result is a collection of writings that is a very deep and broad representation of the large number of papers of my work. The first two volumes are devoted to all the subjects I have worked on, from earliest to latest. These collections (SWAN VIII and IX) are organized in thematic sections somewhat chronologically. We decided to devote the third collection to my writings on deep ecology, because they are the most complete example of a total view that I have been able to offer.

Deep Ecology of Wisdom (SWAN X) is in many respects the most complete volume in the series in that it shows the total sweep of my work. It shows how my comparative and ecological inquiries brought together all my interests and studies. It was also a natural place for me to apply empirical semantics guided by a personal mythology, an undertaking that in the 1990s was offered in my book *Hallingskarvet: How to Have a Long Life with an Old Father*. The Tvergastein article in SWAN X (chapter 33) is an example of the philosophical, empirical, and semantic studies that were saturated with this place through time. SWAN X also includes a comprehensive bib-

AUTHOR'S PREFACE

liography of my works in English, which gives readers the most direct access to this whole body of work. Everything in my work is represented, from Spinoza's philosophy on emotions and Gandhian nonviolent communication, to essays on ontology and mountaineering. All of my work comes together in SWAN X. Readers will see the role of my desire to further nonviolent communication and my scepticism about there being only one worldview that is "true." These reflect my love of diversity.

I have mountain perspectives on worldviews. So many of them are beautiful and so suitable to their places! It is a wonder for me to behold this creative diversity. I found the same on the ground around my hut in the extreme mountain arctic conditions there. Even there, worlds within worlds! In that setting, life energies and mysteries are ever present. I came to approach all research from philosophy to ecology as if I were a field naturalist. This is reflected in my writings. Writing for me is a process of creation, discovery, and systematization; an art that helps me to assimilate and be whole with the more I see, as time goes on, from so many different perspectives. A synoptic view, almost holographic, emerged in my writings in many places. Traveling a lot added to learning these things.

Questions of meaning, preciseness, and interpretation are central to all that I do. We greatly underestimate ourselves in relation to our capacities, but we also greatly overestimate (violently at times) the seeming importance of disagreements over words that are frankly not very precise. The very effort to become more precise is itself an enlightening process that, once started, continues with a natural flow on its own. It is a settled practice that flows through my writing. Gandhian nonviolent communication also runs through my daily writings and practices; it is a second nature. My writings are active engagements, and for this reason I do not find them boring or painful. It is a joy to write about these many subjects that have engaged my passionate interest, especially in relation to the natural world.

Readers of these three volumes of selected papers who want to see my work in a more or less organic way that is roughly historical should read these papers in order, SWAN VIII through X. Those who want an overall look at my whole program of research, writing, and lifestyle should first read volume X. They could also read the last two chapters in SWAN IX, "How My Philosophy Seemed to Develop" and "Deep Ecology and Education: A Conversation with Arne Naess."

AUTHOR'S PREFACE

I have been reflecting on my writings and the way I approach and feel about this work. Let me say something about the different research hares I have chased and the lesser peaks and major mountains I have climbed in the process. I will do this by focusing on a recent ten-year period, from 1987 to 1997.

What has made me eager over the decades to continue writing articles in such great numbers? My spontaneous answer is that these are important questions not only for me but also for everything that it is worthwhile to sustain or develop further. By chance, this very sentence exemplifies a question of this kind: what is meant by “not only for me but . . .” and who is the “me” here? Among such questions there are some to which, as an optimist, I feel I can still contribute. These questions fall into two categories: those related to the ecological crisis and those philosophical questions far away from the ecological crisis. Writing for me is a series of adventures that are part of a larger mythopoetic nature narrative.

I thought that in recent decades the environmental crisis articles would make up the majority of my papers during this time, but to my astonishment that is not the case. For example, in the five years from 1991 to 1995, 61 percent of the articles published [by 1997] deal with general philosophical issues, and 68 percent of the unpublished ones are of that kind. Some of the articles are short, only five pages, which in part explains the large number of articles—78 published and 130 unpublished—during this time. I do very little to get my articles published.

One of the philosophical articles has the title “We need philosophies as life- and worldviews.” Many articles, some used in lectures in various parts of the world, deal with what I hope will characterize university philosophy in the twenty-first century: addressing central questions of what constitutes a meaningful life, diversity of cultures, and the nature of reality. Who are we, where are we, and what do we want most? The last question concerns value priorities. University philosophy, *not* the philosophy of “the man in the street” or of writers in general, has been centered on our talk itself, not on what we talk about. It is often talk about talk. The latest fad has been to stop talking about the variety of conceptions of the world in favor of talking about what are called social constructions, just to mention a focus different from life philosophy and worldviews. (Is nature a big *social* construction?) Clearly, as soon as we start *talking* about anything, for example,

about what is “talk,” what is “social,” and what is a “construction,” we are using a *social* creation, *intersubjective* talking. This does not undermine our excellent, direct relations to the matters we talk about and, I am glad to say, have different views about, some of which are quite personal and individual.

I will not bother to explain all the approaches I have taken within the philosophical sphere. I shall only offer some hints. In ethics I have taught, lectured, and written on the conception of being a “traitor,” a word applied to tens of thousands of Norwegians who in different ways were “on the wrong side” during the Nazi occupation of Norway by Germany. Many who did not deserve it were put in prison. Many believed that Hitler would win the war and that the continued independence and freedom of Norway depended on maintaining good relations with the occupying power.

Norway twice has said “No thank you!” to joining the Common Market, now called the European Union. I have written against joining on the basis of a philosophy that favors cultural differences. The EU is a big step in the direction of economic globalization, a formidable obstacle to cultural integrity and diversity. Some call this effort of mine “applied philosophy,” and I agree.

I have called a class of life- and worldviews *Spinozistic*, and my own view belongs to this class, but that does not *imply* accepting as true or valid any of Spinoza’s axioms and theorems. A long series of my articles deal with Spinoza, especially the central position of strong active emotions as a requirement for increasing our freedom and power, a rather un-Western view! I have explored and written about many Eastern philosophies, including Indian and Chinese. Some of my articles compare Spinoza’s views with Buddhist philosophies.

Gandhian studies continue with what I call the “principles of Gandhian communication,” a form of strict nonviolence. The role of the mass media in tough conflicts makes fairness of central importance. Treatment of an opponent as a fellow human being must be without blemish, even when his views seem to be, or are, horrible, despicable, and idiotic—and even if he is a mass murderer. This treatment is *compatible* with the expression of a strong and honest rejection of the views and actions of an opponent.

Felt suffering has been an important theme in my papers for many years. There is a strange, socially and politically important underestimation of acutely felt suffering and an overestimation of a quantified but not necessar-

AUTHOR'S PREFACE

ily *felt* suffering. If by chance a hundred people living distant from one another simultaneously suffer from a slight headache, this multiplicity of persons does not make the felt suffering stronger. I am deeply interested in the quality, the *feelings* of strong suffering, not some “abstract sum” of suffering.

Suppose we have a chance either to rescue a person from continued, systematic torture or to diminish the slight pain of a million people. As I see it, the choice is ethically unproblematic: rescue the tortured person! Politically, the implication is clear: much greater effort is needed to help people in certain extreme conditions. This, of course, cannot be done without angering dictators. What I call the *intensity principle* in dealing with suffering is generally not considered valid, and the possibility of saving people from continued torture is judged to be very small. As I see it, the problem is that usually only conventional means are considered. We need people with imagination, people like those who rescued thousands of tortured persons during the Second World War and the occupation.

As a philosopher influenced by analytic philosophy and an admirer of mathematical physics, cosmology, and pure mathematics, I regarded the one-hundredth jubilee (1991) of the birth of Rudolf Carnap and Hans Reichenbach as an opportunity to rethink my opposition to their philosophical standpoints and to logical positivism in general. I deeply respect their work, and especially their clearness in the matter of premise-conclusion relations. I have worked hard with a normative system that has only one ultimate normative premise, “Self-realization!” It is a result of the influence of my studies in logic and formal systems. In their work, the logical positivists encouraged each other, discussed with fairness, and used each other’s insights. They were not afraid of real disagreements. This is very unusual in intense philosophical discussions! I try to be fair and cooperate in discussions with my critics in social ecology and ecofeminism.

Going back to the five years from 1986 to 1990, I see that my papers are colored by contributions to the deep ecology movement. There is, however, a notable exception in my writings: what I call *gestalt ontology*. Ontology is an old branch of philosophy that tries to characterize what is real compared to what only appears to be real. Might a birch be bright green and joyful, or is it *really* colorless? Is joyfulness perhaps only a “projection” of joy being felt by an observer? Very roughly, my answer is that *spontaneous experiences* are direct experiences of something real. Joyfulness is

on a par with tallness and specific weight, when we only talk about pure realness. The experiences have a gestalt character. They are complex wholes, not merely atomistic.

The focus on spontaneous experience may be of positive value for deepening and intensifying positive experiences in nature. This focus also accepts the status of negative experiences. If, for example, a city dweller exclaims "Horrible, threatening" when suddenly facing a large waterfall, it is inappropriate to counter with the assertion "You are mistaken. It is really beautiful!" As to the character of being threatening, one might say that it would be a mistake to predict that the water will engulf us. This is just what gestalt ontology says. We can even have a slightly different version; it leads into rather professional philosophical terminologies. Its main thrust radically undermines the claim that only the exact physical sciences show us what is real. On the contrary, they increasingly focus on extremely *abstract structures* of what is real and do not, as sciences, describe any *concrete contents*.

As an outline of my work (from 1987 to 1997), the above gives a rough picture that is a fair description for earlier periods. I should perhaps add a word about my only published book in the 1990s: *Hallingskarvet: How to Have a Long Life with an Old Father* (1995). The main title is the name of a great Norwegian mountain; the subtitle refers to my personal relationship with the mountain. Already at age ten, I looked upon this mountain as being like a wise, benevolent father, but also as a supreme place to live. (My own father died when I was about a year old.) I found in this place an outline of my *mythopoetic life vision*. Many others, I suspect, are today creating such valuable myths of their own. I hope my writings encourage them. If so, these works will serve a useful purpose. So, finally, I am at the end of this written narrative. I invite readers to find their personal paths through this varied and multidimensional terrain of my writings. Follow your own wild passionate feelings.

Arne Naess

II

A Note on the Prehistory and History of the Deep Ecology Movement

The expression originally used for the deep ecology movement was a somewhat longer one: the long-range international deep ecology movement. It was later argued that *long-range* and *international* might be defined so as to be included in the deepness. The original expression makes it not only convenient but factually well founded to start this brief history with the publication of Rachel Carson's *The Silent Spring* in 1963 and the resulting controversies elicited by the cooperation between the U.S. Department of Agriculture and the chemical industry. The controversies revealed political, economic, and technological forces that could engender future silent springs. Rachel Carson went deep and questioned the premises of her society—an essential difference from the argumentation pattern of the shallow ecology movement.

Before 1963, attitudes and opinions corresponding to some of those characteristic of the deep ecology movement are found in many, perhaps practically every culture, and as far back as we have written materials. The deep ecology movement was, soon after *The Silent Spring*, made the object of studies, mostly from special viewpoints. It seems useful, however, to retain a conception that covers all aspects of the kind of achievement Rachel Carson was known for: primarily the warnings about man-made ecological disasters magnified through the involvement of industry and agriculture; secondarily the effort to implement new policies and personal activism; thirdly the philosophical and religious view of life and what makes life meaningful, especially as the basis for an environmentally alert ethics.

The third aspect, the ecophilosophical aspect of the movement, has

This article was written in 1991. It is being published here for the first time.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

motivated the use of the term *deep ecology* for a kind of philosophy and the use of *deep ecologists* as a name of a small group of writers and theorists who use the term and support the movement. The movement is, however, a very broad social phenomenon, essentially comprising all three aspects. It asks for changes in all facets of human life.

The history of the forerunners of the global deep ecology movement and its literary supporters in the United States has been the object of a large group of studies by George Sessions (see, e.g., 1981). Of others contributing to this history, the work by the historian Stephen Fox (1981) and the philosopher Warwick Fox (1990) deserves special mention, but there are also other historical studies on a high level of interest and competence.

The complex European trend of Romanticism from the time of Goethe to the present furnishes rich materials. The history of the cleavage between attitudes and opinions characteristic of those of the deep, socially and politically committed, ecology movement and the reform or shallow ecology movement is closely connected with the history of the interaction between the Enlightenment and Romanticism, especially the background of anthropocentrism in relation to ecocentrism. The Romantic painters were more ecocentric in at least one interpretation of the term. Those terms did convey some information when they were introduced, but very little is left now because of widely different interpretations.

The philosophy of man-nature relations is one of the main features of the history of European philosophy and religion. Of the many works dealing with European background matters, Clarence J. Glacken's *Traces on the Rhodian Shore* (1967) and John Passmore's *Man's Responsibility for Nature* (1974) deserve special mention for their influence in English-speaking countries.

The "discovery" of the mountain wilderness of the Alps was important for the appreciation of territories "of no use" and for the general effort to stop the increase of human territorial domination. A special branch of the general Romantic trend experienced and described Alpine areas as awe-inspiring, superbly beautiful, and, what is still more important, full of intrinsic meaning and value. The areas *communicated* meaning of their own. The landscapes did not need human beings and they did not need to be useful to humankind to justify their existence. The art of painting convincingly showed a turn from admiration of the gardens, the artful and artifi-

cial horticulture of Versailles, the useful and moderate landscapes with human activity and concern at the center, to the admiration of magnificent, self-sufficient landscapes with little or no trace of human purpose. Forests were painted with trees rotting, and life-forms shown that depend upon the presence of “dead” trees.

Wild nature was considered vitally useful for the realization of *human* potentials as soon as the worries of poverty were transcended. Analogous trends had occurred on a vaster scale outside Europe.¹ Recently, the religious meaning of high mountain peaks for the Incas has been brought to light. The old Babylonian culture also made reference to the religious meaning of mountains. “In Mesopotamia, the ‘mountain’ is the place where the mysterious potency of the earth, and hence of all natural life, is concentrated.”²

The art, philosophy, and religions of the East contained trends corresponding to those of European Romanticism. Because of the absence in the East of a uniquely strong rationalist tendency, these trends did not acquire labels like “romantic.” The European Romantic trend in painting is now looked upon *as a form of realism*. It favors a realistic appreciation of human relations to nature. The dominant modern Western trend has been unrealistic and self-destructive.

There is a prevailing ahistorical notion that enthusiasm for and a spiritual cult of the “useless” and “barren” has only been present among the well-to-do. History, however, tells us that just as there always have been poor people traveling to Mecca, there have been poor people struggling to reach and enjoy “hostile” landscapes. Economically reckless feasts have always been a central feature of many cultures. They often left the poor considerably poorer for a long time afterward, but without loss of life quality. One should be careful not to underrate the feelings among the poor for the great and so-called useless. Such feelings may be stronger than among the industrial rich.

The widespread frustrations following the two world wars and the war in Vietnam undermined the arrogant Western notion of progress and its self-congratulatory application of the concept of “advanced society” to a very small part of humanity. A new cultural anthropology emerged with no presumptions of modern Western cultural preeminence.

A work like Marshall Sahlins’s *Stone Age Economics* (1972) opened up vi-

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

sions of economic systems with less stress and the opportunity for deeper cultural activity than those afforded the average person in the richest industrial nations. The new cultural anthropology inspired belief in a future with a wealth of cultural differences proportional to the wealth of human cultural potentials, and compatible with full richness and diversity of non-human life-forms. Cultural anthropology and the study of human cultures show convincingly that gigantic administrations, populations, and technical machinery are not *necessary* as a basis for reaching fundamental human goals and purposes.

All these trends were of importance when the new emphasis on ecology made itself felt in the 1960s. The general prehistory of the deep ecology movement has yet to be written. There is no easy way to establish the roots of a movement, and the identity of the movement itself will always be questionable. The terminology will undergo variation. In any case, much remains to be done to make conscious which forces are operating.

The basically positive function of the ecological crisis is to renew a general concern for what human life is about. What are we here for? To spoil the planet? Why should we do that? Are there any fundamental purposes that make it necessary to endanger the richness and diversity of life? Must we have such a large population of human beings? The so-called shallow or reform ecology movement does not place such questions at the center of our attention. Its adherents do not do that partly because they think the ecological disturbances are few, fairly well known, and capable of elimination by clever management of resources. They also take this approach because they do not combine concern for the Earth with a deeply critical evaluation of the dominant trends in the rich countries. For example, the shallow movement fails to critically evaluate the persistent trend of economic growth and the persistent trend to look at less materially rich countries as "developing" toward the way of life of the rich, as if that would be an unquestionable good. In the deep argumentation pattern, all this is questioned.

Antifascist Character of the Eight Points of the Deep Ecology Movement

The word *fascist* is sometimes used today rather loosely to suggest cruel behavior by a power elite, or a group seemingly intent on establishing such as elite. In what follows I use the word more in the context of fascism as a historical phenomenon. Benito Mussolini was the first to use the term, and his regime was the first fascist regime. However, the national socialism of Adolf Hitler is the best-known fascist ideology.

The central ideological tenets of fascism may be formulated as follows: The strong have always prevailed over the weak and deserve to prevail over the weak. Join the strong! Human destiny and guidelines in the life of the individual are shaped by the state or nation-state, and through racial characteristics. The implementation of policies must be in the hands of the state and is secured through the genius of the leader, who may use ruthless and violent means. The slogan "Freedom, equity, and brotherhood" is unacceptable. There is no brotherhood among races, no equity between leaders and followers. Slogans such as "To believe, to obey, to combat!" are acceptable. In the fight against an opposition, state terror is acceptable.

There are regimes today that deserve to be called fascist and groups with fascist leanings. In many European countries millions still suffer because of the torture, maltreatment, and deprivations they or their nearest experienced under fascist tyrannies, and there is little chance that they will ever completely recover. The adjective *fascist* is therefore rarely used in current political debates except to attack self-proclaimed fascist sympathizers. The reactions were milder in countries that were not directly harmed by fascist forces. There the word is often used very loosely, as a word with

This article was written in 1995. It is being published here for the first time.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

vague but strong negative meanings. In the United States, the expression “environmental fascism” is rarely used, but when it is it naturally awakens the readers’ attention.

It has never been intimated that the deep ecology movement has fascist tendencies in any strict, historical sense of the word. In the broader and wider, popular sense of “fascism,” though, some have warned about possible “fascist” application of the views as they are expressed by deep ecology theorists, and readers ask for clarification.

Fascism values certain collectives higher than the individual (except the Leader): the Nation, the Race, the Party. Although not peculiar to fascism, this view regarding collectives is taken to its extreme by fascists. Some supporters of the deep ecology movement seem to attribute supreme value to an ecosystem, a kind of collective, or to every species. Species are also collectives of sorts, with a vague term, *wholism*, applied to them. Some say that they feel “like a leaf on the tree of life.” This borders on forms of nature mysticism. Philosophers have described the “oceanic feeling,” the feeling of being a drop in a vast ocean. The drop vanishes completely as an independent entity; however, there is no struggle between the drops, no races, no enemies. The image “oceanic feeling” has a very long history but has scarcely ever been used in military pep talks. The fascist collectives do not have much in common with the ocean. Moreover, many supporters of the deep ecology movement only emphasize close interrelationships, not wholism.

Clarification may start with inspecting general formulations that many supporters find acceptable, for example, the Eight Points.

The Eight Points of the deep ecology movement as formulated in Devall and Sessions (1985: 71) are, of course, open to slightly different interpretations. Point 1 makes use of the expression “life-forms.” Some supporters feel strongly, as I do, that intrinsic (or inherent) value attaches to all individual living beings. (It is for me a question of intuition and feeling as much as a question of logic.) The formulation of point 1 that suits me best would, therefore, start with “Every living being . . .” or “All living beings. . . .” It cannot, however, be interpreted as synonymous with “All living beings and *only* individual living beings. . . .” Therefore, it leaves open the question of whether species of other collectives have, or can have, intrinsic value. Actually, many supporters attach intrinsic value to species.

The expression “every life-form” may be interpreted as synonymous with “every individual living being and every species.” What is, or should be, excluded is an interpretation of “every life-form” as synonymous with “every *species* (not every individual living being).”

Representatives of the *science* of ecology have often remarked that supporters of the deep ecology movement underestimate species. Without a species of blue whales, there are no individual blue whales. The threat of extinction of the species is overwhelmingly more important than the threat that a definite individual blue whale faces. Nevertheless, the question of relative importance is not the same as the question of intrinsic value.

The remote possibility of dictatorship in favor of the human species, or of every species, but negation of the intrinsic value of individuals is clearly unacceptable.

When fascist thinkers touch upon the driving forces in evolution, there is a tendency to focus on brutality and cut-throat competition and, of course, an emphasis on the evolutionary value of the stronger eradicating the weaker. Among deep ecology people, the point of view of Peter Kropotkin (1955)—“mutual aid” as an advantage in evolutionary potential—is taken seriously, and so is the general view of Stephan Lackner in his encouraging book *Peaceable Nature* (1984): “Violence causes only 5 percent of death.” This is perhaps too rosy a view, but it deserves close study.

According to point 1, there is a value that is the same for every human being, namely intrinsic value. This is squarely an *antifascist* position. It is incompatible with fascist racism and fascist nationalism, and also with the special ethical status accorded the (supreme) Leader.

How does Green political theory relate to theories of (ethical) *justice*? One may say that they assume or at least presume a conception of justice as fairness, but, of course, they do not find themselves bound to adopt a notion of fairness such as that elaborated by John Rawls (1971) in his careful and influential work on justice. It is, for example, natural within the deep ecology movement to attribute meaning to norms about fairness toward animals. Laboratory mammals are often treated unfairly—the intelligent, “the bright” treated better than the less intelligent, “the dull” ones; the beautiful better than the ugly—and what about distribution of “primary goods”? It is accepted that monkeys may be *made use of* by scientists in ways completely unacceptable if applied to human beings. Yet, those who daily take

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

care of a group of monkeys in a laboratory are expected to distribute available primary and other goods fairly: fair distribution of food and time in playing with them. From point 1, no list of special human rights can be inferred. The points are, it might be useful to repeat, primarily concerned with the specific character of the deep ecology movement *within* the context of the general ecology movement. The acceptance or nonacceptance of a definite list of human rights obviously not accorded to nonhuman beings is *a question of ecosophy*, the total view of a supporter of the deep ecology movement. Theoretically, it is compatible with the Eight Points to be, like Gandhi, skeptical about special human rights. According to Gandhi, human beings have *obligations*, not rights. When he explained what he meant in practice, though, it turned out that we have obligations to behave toward human beings *in accordance with* the doctrines of human (special) rights.

In ecosophical literature there is no sign that supporters of the deep ecology movement reject the list of human rights. On the whole, those writers have not expected that there would be any question of whether they would or would not.

It has been suggested that radical environmentalism, if it gained supreme political power, would perhaps make human interests and human rights subordinate to the well-being of ecosystems. In the 1960s and even in the 1970s, some supporters of deep ecology had a near cultish respect for "mature ecosystems," but since the 1980s the reification of ecosystems has lost scientific ecological credibility. There is recognition of a much higher degree of "chaos," more instability, more complexity in changes. For me to regulate my decisions according to a maxim that a good decision is a decision that is beneficial to the special ecosystem in which I make the decision, is strange and ethically objectionable. A party that tries to develop a cult of ecosystems, or that tries to identify ethics with environmental ethics, cannot be expected to win elections or gain through revolution. Of the hundreds of cares people have, none seems to be connected with the rather abstract doctrine of life and death of ecosystems. They may learn about vast and important relationships. If they depend on fish from the Barents Sea, they learn that the population of fish they buy depends upon the population of other species and upon the policies adopted, that is, upon the necessary restrictions and solutions of international conflicts related to them: ecosystemic knowledge. They may support ecologically responsible

policies, but they may not believe in the intrinsic value of the system. Ecosophies are total views in part inspired by the crisis, but even if people accept an ecosophy, the part played by ecological consideration will be very small. I don't think we should wish it to be otherwise.

By attributing intrinsic value to nonhuman beings, deep ecology supporters may be said to accept a widened Kantian maxim: no living being should be treated *merely* as a means. The wideness of the application of the predicate *living* is, of course, open to different proposals. It is, for example, not necessary to include the HIV virus.

Applying point 1 to human beings, I derive, as already mentioned, the formulation "Every single human being has intrinsic (inherent) value (worth)." I hesitate, though, to derive "Every single human being is worthy of *respect*." I hesitate because, for example, I would not say I *respect* a torturer. It is meaningful for me to say that I can do something for a torturer, something for his own sake. As a matter of course I offered a torturer tea when he was being interrogated. After a long interrogation, he asked whether I could help him get shot immediately instead of being kept in solitary confinement for a long time. I did not have the power to make the authorities shoot him immediately as he requested, but perhaps I would have asked them had I had the power. A human being should be treated according to certain standards even if he has been a torturer. There are strict rules as to how to behave toward a prisoner, whatever his crime. He remains a fellow human being. *Special obligations* are due to one's fellow human beings.

When people accused of torture were imprisoned in 1945, they were visited by people from the Resistance and especially by Christian priests. These visits did not indicate any softness in regard to the dreadful character of the prisoners' *deeds*. Sometimes the terrible character of what they had done made the visitors look upon them as the most *miserable* beings on Earth. People may be classed in regard to valuableness for the community or for innumerable other purposes. Point 1 does not concern instrumental value, nor the question of whether there are different sorts of inherent value. What about gradation, though?

Point 1 does not *imply* any notion of quantification or gradation of intrinsic value. It does not imply *equity* as opposed to "more or less." Nor does it *imply* the absence of gradation.

Some supporters introduce gradation: human beings have more or

higher intrinsic value than other living beings. Mammals have higher intrinsic value than insects. It is difficult to avoid rather complex systems of gradation. The more they are intellectually elaborated, the farther they recede from the more or less intuitive basis that I have for attributing the same value, the intrinsic value, to every living being.

Instead of grading intrinsic value, some of us grade obligations—abysmal differences of obligations! In the case of obligations as well, a *complex* system of strong and weak obligations lacks a clear intuitive basis. One cannot expect intercultural consensus. As I see it (that is, according to Ecosophy T), human beings have more and very much stricter (ethical) obligations toward human beings than toward nonhuman beings. Parents have more and stricter obligations toward their own children than toward other people's children. Geography and access come in as well: nearness and ease of reach are factors. The intrinsic value of children is one and the same. That children die of hunger is unacceptable, whatever the geographical distance. In other words, there is an ethical obligation to support measures to eliminate the phenomenon. The same applies to the systematic torture perpetuated in many countries.

From the fact that supporters of the deep ecology movement are supposed to be motivated (in part) by their philosophical or religious beliefs, it does not follow that their decisions are *determined* by the Eight Points. The decisions should be consonant with their *ecosophy*, their total view, something immensely broader than the Eight Points, although it may include the Eight Points. At North-South conferences it sometimes happens that people from the Third World imagine that the Eight Points are meant to give an adequate basis for their decisions. Rightly, they object that ecological problems cannot and should not have the highest priority in their countries. If being a supporter of the deep ecology movement implies having such a preposterous view, nobody in the Third World could possibly be a supporter—nor should anybody anywhere interpret the Eight Points that way. They focus on some differences between the outlook of a certain group of *activists* within the general ecological movement and the rest—and the Eight Points concern matters relevant to overcoming the ecological *crisis* largely caused by the rich nations, which have the duty to clean up. So much about point 1, and the relation between the Eight Points and their antifascist, pro-Third World character.

In any movement that promotes serious changes affecting all aspects of society, one should be on the outlook for supporters who might ask for dictatorial or authoritarian measures. None of the theorists of deep ecology show any such tendencies. Moreover, nobody who strives to be a dictator is likely to profit from letting every human being be treated as having the same inherent value. Nevertheless, many supporters warn us: the longer we wait before responsible ecological policies are adopted, the more likely there may develop catastrophes that prepare the ground for undemocratic measures.

Point 2 announces the intrinsic value of richness and diversity of life-forms. In the formulation of this point in Devall and Sessions (1985), the diversity of human cultures is not mentioned. More recent versions announce that such diversity should be included under the heading “diversity of life-forms” and thereby accorded intrinsic value. That is, the addition should not necessarily be included in the formulation of point 2 but in the “first-order comments.”

By first-order comments I mean precizations: specifications and elaborations that are clearly needed to ensure that the “point of departure” eight-point formulations are interpreted as intended. Such comments ought not, I think, to comprise more than about four hundred words, double the number of words in the Eight Points. The second-order comments may use twice as many words again, that is, eight hundred words. I mention this to emphasize that if we assume that the eight-point formulations are read by people with greatly different backgrounds and emotional attitudes toward questions raised by the deep ecology movement, one must expect to talk at length to convey the intended meaning of the formulations. Moreover, this discussion may give, and has given, good suggestions for how to improve the formulation of the Eight Points, or how to work with completely different sets of formulations.

Intrinsic value has an important limitation: some cultures have as a basic feature an intolerance toward others. This intolerance and discrimination is characteristic of fascist ideology. The democratic political culture has regularly been the object of hateful and derisive criticism.

One fairly obvious and easily made change in the formulations is the following. In point 8 these words may be added: “by peaceful and democratic means.” Some have objected to the use of the term *democratic* because

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

of the obvious imperfections of contemporary democracies. I think, though, that the term can be saved from being completely identified in meaning with contemporary democracies. Point 8 then might read: "Those who subscribe to the foregoing points have an obligation directly or indirectly to try to contribute to the implementation of the necessary changes by peaceful and nonviolent means."

In regard to nonviolence, as contrasted with the fascist masculine pugnacity, supporters of the deep ecology movement are criticized because they do not answer strong attacks. They are often called meek and pacifist. Thus, when Murray Bookchin (1980) started somewhat wild and immoderate attacks on deep ecology, there were no corresponding counterattacks. The attacks did not elicit polemics *between* the two camps, the social ecologists and the supporters of the deep ecology movement. On the whole, the latter only continued to *explain* what they stood for. Even in the published debate between Bookchin and the "wildly radical" supporter of the deep ecology movement Dave Foreman (Bookchin, Foreman, and Chase 1991), there is a characteristic mildness in the latter's formulations. "The best defense is the attack" is not always good advice. One should, of course, attack, using Gandhian rules of verbal communication; that is, one should carefully formulate counterarguments against the views of the attacker, not only defend one's own. As regards the relation of the two movements, the social ecology and the deep ecology, it is obvious that one may support both. The latter is broader, more diffuse, *some* will say.

Some critics do not believe in the danger of fascist tendencies in the deep ecology movement. They do not see any possibility that *authoritarian* policies could be established if the supporters became powerful—for example, that the supporters of the shallow or reform movement might be suppressed, even put in prison. Even today, the peaceful collaboration of the two parts of the general movement is a necessity. Most of the many hundreds of professionals involved in the questions relating to climatic changes are, as far as I know, fairly uninterested in ultimate premises. The supporters have no chance to "take over" the climate studies, either now or in a future when (hopefully), thanks to all activists in the *general* ecology movement, the ecological crisis has been overcome.

The 1980s and early 1990s saw a series of valuable contributions to so-called *Green* political theory as something different from mere *green* politi-

cal theory.¹ A few examples are Hazel Henderson's *Politics of the Solar Age* (1981), Fritjof Capra and Charlene Spretnak's *Green Politics* (1984), Jonathan Porritt's *Seeing Green: The Politics of Ecology Explained* (1984), John Dryzek's *Rational Ecology: Environment and Political Ecology* (1987), Robert C. Pauhke's *Environmentalism and the Future of Progressive Politics* (1989), Andrew Dobson's *Green Political Thought* (1990), Robyn Eckersley's *Environmentalism and Political Theory: Toward an Ecocentric Approach* (1992), and Robert Goodin's *Green Political Theory* (1992). Do these authors display fascist tendencies? No. Threats against the vital rights of human beings? No.

I agree with those who think that there is too much talk about the Eight Points. It is a sign of imperfect clarity about what deep ecology is all about. The situation makes it necessary to repeat over and over again some points that unite the great diversity of people who *feel* that they strongly agree with lots of the things that are said and done with reference to "deep ecology." To bring the Eight Points into the discussion may be helpful and convenient, but, of course, they do not furnish an adequate picture of the movement.

Deepness of Questions and the Deep Ecology Movement

Historical Perspective

Whatever the weaknesses we are all aware of, the term *deep* is going to remain central in the terminological structure of the deep ecology movement.¹ Is the deep ecology terminological structure complicated? It is nothing compared to what we have to get accustomed to if we participate in social and political debates. Here, I focus on only one approach in trying to make the term *deep* more precise in the relevant sense (thus eliminating interpretations that lead away from what is intended). The approach taken here is concerned with premise-conclusion chains.² This approach is concerned with the *deepness of premises* used in debates over efforts to overcome the ecological crisis.

There are other approaches—for example, the “deepness and broadness of attitude” approach. Let us say that the owner of a rock garden may treasure every life-form in the garden for its own sake, but this attitude is limited only to the garden. The attitude is not deep enough for this person to generalize it beyond the confines of the garden. Further, the shortcomings of society may be seen and felt by this person, and result in unrest and frustration, but the attitude is not intense enough to make the owner of the garden “problematize” all aspects of society. Whereas the premise-conclusion approach, if carried out systematically, requires some educa-

This article was reprinted with permission from *Deep Ecology for the 21st Century: Readings on the Philosophy and Practice of the New Environmentalism*, edited by George Sessions (Boston: Shambhala Publications, Inc., 1995), 204–12.

tion (but not knowledge) in logic, the “deepness of attitude” approach leads to social psychology and social science in general. However, only a small group of a movement’s theorists can afford to spend much time on systematization.

Conservatism may be said to be the social movement that tries to conserve what is best in what already exists. Such short expressions of what a social movement “is” may have some value in some contexts, but generally a social movement requires fairly complex characterizations. Attempts to shorten them into one sentence, which is then treated as a so-called definition or criterion, are rarely successful—or the sentence gets to be too long and complicated. Definition may have a place in dictionaries, but rarely elsewhere.

In my paper “The deep ecology movement: Some philosophical aspects” (1986; see chapter 5 in this volume), the contrast between the deep and the shallow ecological movements is characterized in about two hundred words. One difference is said to be decisive: it “concerns a willingness to question and to appreciate the importance of questioning every economic and political policy in public.” The questioning is “deep” and “public.” Because I used the word *questioning*, not the Germanic *problematizing*, the misinterpretation arose that I found intellectual playful questioning of the kind encountered in graduate philosophy seminars sufficient. On the other hand, problematizing is a profound “existential” undertaking.

When one compares the two movements, however, the relatively deeper questioning in the sense of “problematizing” (*Problematizierung*) of the deep ecology movement is quite manifest. It is my *hypothesis* that any systematic contemporary philosophy will, if it takes a stand on the ecological crisis, support the deep ecology movement. Supporters of the deep ecology movement, therefore, have no systematic philosophy to oppose. The modern ecological predicament is the result of thoughtlessness rather than thought. In one sense we may say: if there is deep questioning, then this is compatible with Ecosophy T, or some other ecosophy articulating the perspectives of the deep ecology movement. “Deepness,” however, must include not just systematic philosophical deepness, but also the “deepness” of proposed social changes.

Persistent “Whys” and “Hows”

Let us inspect the chain of questions in the following dialogue:

1. A: Turn on the gas!
2. B: Why?
3. A: Because we are going to boil the potatoes.
4. B: Why?
5. A: Because we ought to have dinner soon.
6. B: Why?
7. A: Because we should keep fit.
8. B: Why?
9. A: Because we should do what makes us feel happy.
10. B: Why?
11. A: Because happiness is what we ultimately desire.
12. B: Why?
13. A: “Happiness” means satisfaction of all biological and social needs.
14. B: Why?

At step 13 the pure why-chain turns from normative to descriptive. This may lead us into discussing the etymology of the term *happiness* and other unphilosophical specialties. The “whys” at 10 and 12 are within the traditions of philosophy and more profound, I would say, than at 8 or even at 14. Furthermore I would say, perhaps arbitrarily, that the “why” at 8 is more profound, or leads (or may more easily lead) into deeper water, than the “why” at 6. It is convenient to use two words here, *deep* and *profound*, letting *deep* refer to the premise-conclusion relations and letting *profound* refer to nearness to philosophical and religious matters. The latter term I leave unanalyzed.

At the start of introductory philosophy courses, my habit of persis-

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

tently asking why, whatever the answers to my questions (for example, “What time is it?”), makes the students bemused, bewildered, frustrated, or angry in a remarkably fruitful way for the whole course. In less than ten minutes, they are ready for anything.

Among other things, they realize that deep questions seem to be only “millimeters” away from the trivial, conventional, or silly. Some become unhappily bewildered because they feel that I am making fun of them, or that their sanity is being tested.

The unhappily bewildered remind me of the research on “tolerance of ambiguity” in the 1930s and 1940s motivated by the astonishing popularity of fascist and National Socialist ideas. One working hypothesis held that intolerance for the ambiguity of a situation correlated highly with indicators of acceptance of fascist ideas: that there should always be rules for correctness. The only test for saneness is correctness: to be *comme il faut*. Certain questions could (should) be asked, others could not. Idle wondering is dangerous, therefore “keep straight at any cost.” The fuhrer establishes the rules, thereby avoiding *embarrassing* bewilderment.

Suppose the above dialogue, at an early stage, went descriptive, and explanatory:

1. A: Turn on the gas!
2. B: Why?
- 3b. A: Because if you do not turn on the gas the water will not boil.
- 4b. B: Why?
- 5b. A: Because cold water needs heat from the gas in order to reach boiling temperature.
- 6b. B: Why?
- 7b. A: Boiling requires that water molecules attain higher velocities and these must be transferred from the hot flame of the gas.
- 8b. B: Why?
- 9b. A: Because, ultimately, quantum mechanical and thermodynamical laws prescribe certain conditions to be fulfilled.

10b. B: Why?

11b. A: We have no good reason to think that heating might be done otherwise than in conformity with physical and chemical laws or theories accepted today.

12b. B: Why?

Again, we have landed in philosophy. Why-strings in science inevitably lead us beyond science. Sequences of “how?” show similar traits. Sooner or later we arrive at fields of inquiry typical of philosophy.

1. A: Turn on the gas!

2c. B: How?

3c. A: Put your fingers here and turn to the left.

4c. B: How?

5c. A: Activate certain muscles of your underarm . . . !

6c. B: How?

7c. A: By deciding to do so.

8c. B: How?

9c. A: Pull yourself together!

10c. B: How?

11c. A: Use your free will!

It seems that we can lead a dialogue out of philosophy even when continuing our whys and hows, but not without certain kinds of diversionary steps or sidetracking maneuvers:

12c. B: How?

13c. A: By a careful study of the philosophy of personal development.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

It might be possible to keep the dialogue within the borders of techniques of study a couple of steps farther, but roughly the conclusion holds that persistent questioning leads to deeper questions.

The importance of this conclusion is limited because whereas question number n may lead deeper, question $n+1$ may lead back to trivialities as exemplified by 12c. We must consider, too, which concepts of “depth” are intended? “Deep mathematical theorems” are one thing; “deep grammatical structure” is something else. Is philosophy invariably deep? Deep waters can be distinguished from murky ones, but how are deep questions and answers distinguished from murky ones? Let us say the dialogue takes this turn:

x . There is something rather than nothing.

$x+1$. Why?

$x+2$

Some of us will characterize the Heideggerian literature at step $x+2$ as murky rather than deep, or at least as both murky and deep.

In a critical situation, a complex proposal A (concerning how to act) may be said to be based on a set of premises, some of them explicitly formulated in A , the others playing the role of unarticulated “presuppositions” (Collingwood 1948). Suppose a proposal B is based upon the same set of premises except one, an unarticulated presupposition P . B questions (problematizes) P , does not find it tenable, and rejects proposal A . In this critical situation, B may be said to *question more deeply* than A , and the deeper question may be said to be “Why P ?”

The above is meant just to touch upon the difficult questions we face when trying to formulate fairly simple (but useful) analyses (precizations) of “deep questions,” “deeper questioning,” and similar expressions.

These questions do not, in my view, undermine the usefulness and appropriateness of the designation “deep ecology movement,” but they do justify the remarks made by Warwick Fox, David Rothenberg, and others, that what deep ecology theorists write is often sketchy, tentative, and preliminary (using my words rather than theirs). Theoreticians for the peace movement, and especially the Marxist-inspired social justice movements, have produced much heavier thought together with highly elaborated doc-

trines. Unfortunately, the widening of the ecological crisis seems to give us more than enough time to gain in profoundness.

Comparing argumentation patterns within the shallow and deep movements, I find that although supporters of the deep ecological movement (as characterized in certain texts) ask deeper questions, they are rarely zetetics—questioning everything. On the contrary, like Rachel Carson, they tend to have firm convictions at a deep level. This is also true of people in the other two great movements—the peace and social justice movements.

Inspecting my examples of why- and how-strings, some might wonder: are they not also suited for introducing concepts of “*p* being sillier than *q*”? This question reminds us of the concept of *relevance*. When questions of what to do (or not to do) in a given situation are relevant, why- and how-strings sooner or later become irrelevant. They get sillier from the point of view of action. For example, if we start a string of questions and answers concerning why and how we eat, eating becomes more and more relevant as the hours pass. Action (in this case, eating) cuts the Gordian knot but leaves all questions open, and leaves all answers invoked to account for decision and action questionable.

For example, the main reaction of the U.S. Department of Agriculture and the chemical industry to Rachel Carson’s accusations in *Silent Spring* (1962) was “Wildly exaggerated!” If this factual and normative premise is accepted, then the questions raised by her are clearly irrelevant, and some of them are even silly. From 1963 to 1989 there have been vast differences of opinion concerning the gravity of the ecological situation. One may roughly distinguish an extreme optimism, a moderate optimism, a moderate pessimism, and a black pessimism (the “doomsday prophets”). The supporters of the deep ecology movement consider the ecological crisis to be grave, and this may be seen by some as pessimism. Tremendous efforts will be necessary, and the transition to wide ecological sustainability will be painful for most people. The supporters of the shallow movement tend toward optimism. Some do not even acknowledge that there is anything like a crisis but support vigorous action to investigate the ozone layer situation, to restore forests with genetically altered trees that grow faster and are more resistant to pollutants, and other kinds of repair jobs. Some of these efforts are admirable and indispensable today from the deep ecology standpoint.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

The tendency to refrain from discussion of deep questions in the shallow movement has, as its main cause, the perceived irrelevance of such discussion: why bother? The supporters of the shallow movement believe that responsible ecological policies will be implemented in due course because of the clearly manageable magnitude of the implied problems.

When the use of pesticides was increasing by a very large percentage each year, only a few people were alarmed, and they soon found that strong forces were allied against the use of restraint. Even when the short-range undesirable consequences of pesticide use became clear, nothing decisive was done to change the situation.

Few people persistently asked why or how. Those who did, however, were deeply concerned about the ecological consequences. The answers to these questions relate not only to chemistry and biology; they involve increasingly more and more spheres of human affairs—economic, technological, social, cultural—and ultimately, philosophical and religious levels. That is, those who went deeper both *questioned more deeply* (in the sense of deeper premises) and *suggested deeper changes socially* (in a wide sense).

The percentage increase of the sheer volume of impact, and the increase of pernicious impact (of special chemicals, especially on vulnerable regional changes), could not, and cannot, be precisely measured. There is always room for differences in degrees of optimism and pessimism. The effects of DDT were uncertain; the causes and effects of acid rain are still uncertain; climatic changes (ice age or warming of the planet, or both, or none?) are uncertain. Some point out that population growth correlates with the growth of wealth if proper technology is available—look at the history of Holland! With high income and education, population stabilizes. The implication is that there is no cause for alarm.

With moderate degrees of optimism the why- and how-strings need not be long. Science and technology seem to furnish answers; also they do not touch fundamental social conditions, nor fundamental attitudes and value priorities.

The difference between the deep and the shallow ecological movements may be looked at from a special point of view, namely, what is questioned and how deep the questioning goes, although *defining* the movements in terms of deepness of questioning is misleading. The English term *questioning* is not as forceful as the Germanic and French equivalents: *prob-*

lematizieren, *Problematizierung*, *problematique*, etc. In European philosophy and politics during the late 1960s, these terms were important—the whole industrial society was questioned: *problematiziert*. The movement to protect nature was *politiziert* in the sense that it had to face the economic and political forces that mobilized against major protection efforts. Without political changes there would be no shift to ecologically sane policies. In the United States, terms like *vested interests* and *hidden persuaders* were used but did not gain much influence in questions of environmentalism. The profound *Problematizierung* of the sociologist C. Wright Mills (1967) came too early.

Looking at the relevant literature and public debates, my conclusion is (and has long been) that what characterizes the deep movement (in relation to the shallow) is not so much the *answers* that are given to “deep questions” but rather *that* “deep questions” are raised and taken seriously. Argumentation patterns within the shallow movement rarely touch the deeper questions: we do not find the complete social and philosophical *Problematizierung*. However, if supporters of the shallow movement are invited to answer the deeper questions, it is my experience that they often accept the points of view of the deep ecology movement. (A pilot study³ in which influential people were invited to answer these kinds of questions confirms my impressions. More studies of this kind would be highly desirable.)

From this I conclude that the view is untenable that one is confronted, in the ecological crisis, with politicians and other influential people who invariably hold a different philosophy of life and a different view about humanity’s place in the cosmic scheme, and who deliberately work against the realization of a green society (which implies respect for the richness and diversity of life on Earth). They often say, “Yes, sure. Every living being has intrinsic value, but what is your politically realistic proposal for solving the unemployment problem? Some forests may have to go.”

The last few years have seen a lively interest among religious leaders in denouncing the arrogance toward, and ruthless exploitation of, the planet. Christian leaders proclaim the intrinsic value of all beings because they are the creation of God, and speak about human sinful behavior toward God’s creation. There is a central point, however, that this “new green wave” on the philosophical and religious level has not taken sufficiently seriously: *the necessity of a substantial change in economic, social, and ideological structures*. If

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

the first five points of the deep ecology platform are accepted, such changes are seen as necessary by most supporters of the deep ecology movement (cf. especially point 6).

Should we now say, then, that deeper questioning is no longer what fundamentally makes deep ecology argumentation patterns different from those of the shallow movement? The term *fundamentally* is too strong. I think *most clearly* is better.

I introduced the concept of pure why-strings to illustrate the simple concept of “deeper question,” which was adapted to one of the many usages of the term *deep*. There is, however, another usage relevant to the choice of the designation “deep ecology movement”: that of *deepness of change*. Whereas the shallow movement suggests increases in environmental budgets, forcing polluters to pay for their pollution, and many other changes in social policies, these proposed changes are not “deep.” Green political party programs usually imply changes on the same deep level as those implied by the deep ecology movement.

As an example, let us consider the philosophical norm of universalizability as applied to ecological policies. Because all major ecological problems are global as well as local, one society degrading the Earth to a much greater extent per capita than other societies cannot be tolerated as long as the global volume of interference is clearly excessive. Norms of justice derivable from the Eight Points may convince people that ethically justifiable levels of interference in ecosystems require much deeper social changes than are now widely anticipated. Societies must adopt policies that can be universalized without reducing the richness and diversity of life on Earth.

It is of considerable importance that the deep ecology movement has so far faced no serious philosophically based criticism. Sooner or later that will occur, but of course it has to be legitimate criticism, not a caricature of the movement.

Jeremy Bentham was both a philosopher and a social reformer who was not afraid to derive very special particular norms from general principles; for example, which color would be best for ballot boxes. For every British custom and legal procedure he asked “Why so?” If a procedure did not satisfy his pleasure principle, it was to be abandoned. That is, he questioned (problematized) every procedure in the light of his total view, his special form of utilitarianism. Even if his way of doing this (through his “special”

why-strings) was fictitious to some degree (like the *q.e.d.*'s of Spinoza's "proofs"), his reform movement was highly successful.

The ecological crisis requires an analogous scrutiny of "everything" in the light of broad, global long-range ecological sustainability. Here, why- and how-strings must mercilessly confront procedures with basic principles on the philosophical and religious levels.

Equality, Sameness, and Rights

My intuition is that the right to live is one and the same for all individuals, whatever the species, but the vital interests of our nearest nevertheless have priority. The rules that operate when interests conflict include two important factors: vitalness and nearness. The greater vital interest has priority over the less vital, and the nearer has priority over the more remote—in space, time, culture, and species. Nearness derives its priority from our special responsibilities, obligations, and insights as human beings among human beings.

The terms used in these rules are of course vague and ambiguous, but even so, the rules point toward ways of thinking and acting that do not leave us helpless in the many inevitable conflicts between norms. The vast increase of negative consequences for life in general, brought about by industrialization and the population explosion, necessitates new guidelines.

For example, the use of threatened species for food or fur clothing may be more or less vital for certain poor families in nonindustrial human communities. Among people who are not poor, however, such use is clearly ecologically irresponsible. Given the fabulous possibilities open to the richest industrial nations, it is their responsibility to cooperate with poor communities such that undue exploitation of threatened species, populations, and ecosystems can be avoided.

It may be of vital interest to a family of poisonous snakes to remain

This article was reprinted with permission from *Deep Ecology for the 21st Century: Readings on the Philosophy and Practice of the New Environmentalism*, edited by George Sessions (Boston: Shambhala Publications, Inc., 1995), 222–24.

where they have lived for hundreds of generations but where small children now play, but it is also of vital interest to the children and their parents that there be no accidents. The priority rule of nearness (and a sense of responsibility) makes it justifiable for the parents to relocate the snakes. However, the priority of the vital interests of the snakes is important in deciding where to establish the playgrounds in the first place.

A personal testimony: I have injured thousands of individuals of the tiny arctic plant *Salix herbacea* during ten years of living in the high mountains of Norway, and I shall feel forced to continue stepping on them as long as I live there. However, I have never felt the need to justify such behavior by thinking that they have less right to live and blossom (or that they have less intrinsic value as living beings) than other living beings, including myself. It is simply not possible to live and move around in certain mountain areas without stepping on myriads of these plants, and I maintain that it *is* justifiable to live in these mountain areas. When I behave as I do, I can (at the same time) admire these plants and acknowledge their “equal” right to live and blossom with my right to do so: not less and not more. It is therefore a better formulation to say that living beings have a right (or intrinsic or inherent value, or value in themselves) to live and blossom that is the *same* for all. If we speak of differences in rights or value, we do not speak of the rights or value I have in mind. It is not meaningful to speak of *degrees* of intrinsic or inherent value when speaking of the right of individuals to live and blossom.

What I have done here is try to verbalize an intuition, although any such verbalization may be misleading, and this one has certainly often misled others. There are other intuitions and thousands of slight differences in attitude reflecting different valuations of various sorts. For example, if there is a choice of whether to step on a *Salix herbacea* or on the rarer, more overwhelmingly beautiful *Gentiana nivalis*, I unhesitatingly and deliberately step on the former.

The abstract and somewhat grandiose term *biospherical egalitarianism in principle* and certain similar terms that I have sometimes used perhaps do more harm than good. They may be taken by some to suggest a major *doctrine* of sorts, but that goes way beyond my intentions. As I see it, the importance of the intuition I speak of resides in its capacity to counteract, perhaps only momentarily, the self-congratulatory and lordly attitude to-

ward those beings that may seem, to some people, to be less developed, less complex, less beautiful, or less miraculous.

When I characterize this as an intuition, I do not imply the absence or lack of a rational basis for it, but rather that there are other factors operating here. For example, the increase in demand for rigor in mathematical proofs eliminated certain intuitions. But intuitions still operate, as when mathematicians choose axioms and other fundamentals.

A rich variety of acceptable motives exist for being more reluctant to injure or kill a living being of kind *A* rather than kind *B*. The cultural setting is different for each being in each culture, and there are few general norms—only vague general guidelines. The more narrow and specific the questions posed, the less vagueness there will be. For example, I have proposed norms relating to communities of bears, wolves, sheep, and sheep owners in Norway.¹

Another relevant factor is the *felt nearness* of different living beings. This factor largely determines our capacity to identify strongly with certain kinds of living beings, and to suffer when they suffer. One cannot put forth ethical rules of conduct without taking our limited capacities, and such personal feelings, seriously. If it is difficult to avoid killing *A*, for example, because of its smallness, whereas killing *B* is easily avoided, then we tend to protect *B* rather than *A*. Moreover, there is an obvious diversity of obligations. We have special obligations toward our own children: any animal may be killed in order to feed one's starving child. Obligations toward individuals that have been members of our communities for long periods of time are greater than toward accidental visitors. Furthermore, there is, of course, the relevance of suffering: Is the suffering of *A* less than that of *B*? Does *A* have the capacity to suffer?

The rather simple thing I am trying to convey here is that an ethic that attempts to deal with the *differences* between nonhuman living beings is on a comparable level of complexity with an ethic that concerns itself with our behavior toward the people and groups with which we interact.

Related to the above, I prefer the term *living being* to the term *organism*. The intuitive concept of "life" (or "living being") sometimes includes a river, a landscape, a wilderness, a mountain, and an arctic "waste." The intuition has a little, but not much, to do with biology or neurophysiology. Intrinsic value, as posited by the intuition, is influenced, but not decisively,

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

by “biological news”: for example, news about the whale’s nervous system complexity being comparable to that of human beings.

The kind of intuition I have been speaking about I take to be rather common among supporters of the deep ecology movement. It is not easy to verify this in detail, however, because of terminological and conceptual differences. The broad stream of nature poetry, over thousands of years, is perhaps the best source of confirmation of the widespread intuitive appreciation of the *same* right of all beings to live and blossom.

Nature Ebbing Out

Some people grasp a great new thought quickly and completely, but most of us take somewhat longer. I am one of those who has finally understood that ours is perhaps the last century in a very important respect. The spectacular, free, beautiful, and “dangerous” nature is about to disappear. Our children will live in a domesticated world in which everywhere they go, they will see human faces instead of the overwhelming face of nature. Even the giants of the Himalayas are being tamed. Helicopters buzz along the flanks of Daulagiri; soon technology will enable them to buzz around the highest summits.

The problems of protecting the environment are beginning to be taken up in Norway. Here, though, people’s attitude regarding natural resources seems to be that we still have more than enough. Those who support the exploitation of “our” resources probably think as Little Hans did when his mother warned him that if everybody stole, society would crumble and fall apart, and Little Hans said, “You are right, Mother, but society can very well endure that *I* steal!”

For those who watch the development in Norway with concern, it is a consolation to see how far environmentalists have come in the United States, where resistance has been stronger. Despite this resistance, they have managed to achieve more than anywhere else in the world, particularly in the domain of protecting national treasures. When it was rumored that the Grand Canyon would be declared a national park, a certain Mr. Cameron hastened to put “claims” (i.e., mineral excavation rights) on

This article, a plea to protect Innerdalen, a mountainous area on the west coast of Norway, was written in 1965 and translated from the Norwegian (“Natur ebber ut”) by Kit-Fai Naess. It is being published here for the first time.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

places where one could get down into the canyon. His intention was to exact a toll from tourists, not extract minerals. This piece of private enterprise came to be looked upon as very smart. As it turned out, it was difficult and costly to get Mr. Cameron out of the Grand Canyon, although the authorities at last succeeded. Then, in 1920 when Cameron was elected to the Senate to represent Arizona, he avenged himself by making the grants for environmental protection extremely low. Even now it is considered good sport in some circles to buy up real estate in a rush and repair the buildings therein when it is rumored that the region is to receive "protected" status. It is assumed that the government will purchase the property at exorbitant prices.

Private enterprise is no longer the only obstacle. Environmentalists must now have expertise in law and social research. Until recently there were between forty and fifty governmental institutions in California alone that had in their power the ability to change the face of the country—and their activities were uncoordinated. Those who want to protect something must have an overall view of what is happening everywhere in order to forestall actions detrimental to the environment. The mighty Department of Transportation in the United States has control over a land area bigger than the whole of Norway, and to avoid too-broad, too-flat roads in protected mountain areas, one has to seek the personal blessing of the President.

The tangle of modern bureaucracy can be charted, but in recent years a major difficulty has arisen: every unused waterfall or log must be transformed into something that can be measured quantitatively. Its value must be registered in a computer, or else this magnificence of nature, this grandeur, cannot appear in tables and charts showing the country's riches and resources. Well-meaning economists have carried out this miracle of measurement for us. The music of Schubert and Beethoven is still played, hundreds of years after their death. With the proceeds from the performances of these composers' songs and symphonies through the years, we can calculate the use-value of certain phenomena, be they pieces of music or national parks. From this, the road to measuring the total value of nature areas is short. It is enlightening that the figures one comes up with are very satisfactory, convincing enough for the many who want "facts," not just romantic or impractical talk. We must not forget that people's usual concepts about resources, energy, and richness cover exactly the things that only

have value as means, things that *are not good in themselves*. What is and has always been perfectly good for itself, that which *cannot* be divided and quantified in dollar values, will be excluded from the calculation.

These are just a few words about the difficulties that, in many respects, have been overcome. We all have heard about America's wonderful Yellowstone National Park, Yosemite, and so on, but not everyone is aware that there are more than eighty wilderness areas of differing "degree of purity" where, for example, there are no buildings or roads. For Norway the fight for such areas ought not to have such a high priority yet, but the thought itself is of great importance. Wilderness areas give expression to the value of nature as something *totally* untamed.

When I think about how difficulties are overcome in other places, and how high our own Innerdalen ranks on whatever scale one chooses—beauty, easy access, or magnificence—I hope that its preservation will soon be a reality. If I were asked to name a characteristic of Innerdalen that surpasses all other characteristics, I would say it this way: maximum beauty or splendor *per cubic meter*. The landscape changes exceptionally fast when one moves in its terrain, and the distance from one wonder to the next is very small!

The Apron Diagram

Overview

I see the deep ecology movement and its supporters as part of a total view that comprises many levels and many ultimate philosophies and diverse practices in close contact with one another. To illustrate this I use an “apron diagram” (figure 2), which illustrates logical, as distinct from genetic, relations between views. By *logical relations*, I mean verbally articulated relations between the premises and conclusions. They move down the diagram in stages: some conclusions become premises for new conclusions. By *genetic relations*, I refer to influences, motivations, inspirations, and cause-and-effect relations. They are not indicated anywhere in the apron diagram. They may move up and down or anywhere, and they involve time.

The platform principles of the deep ecology movement can be grounded for individual supporters in a religion or an ultimate philosophy. The religions and philosophies from which people can support these principles are many and diverse. In a loose sense the movement can be said to be derived from these kinds of fundamentals. The situation reminds us that a set of very similar or even identical conclusions may be drawn from divergent premises. The platform can be the same, even though the fundamental premises differ. One must avoid looking for one definite philosophy or religion among all the supporters of the deep ecology movement. Fortunately, a rich manifold of fundamental views are compatible with the platform of

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

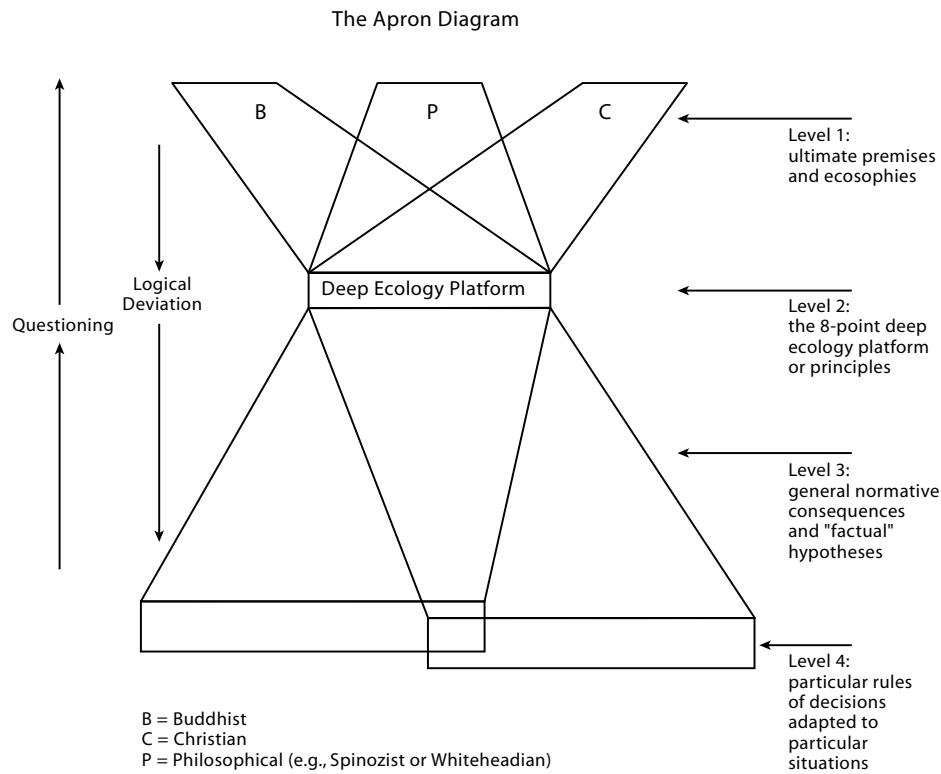

Figure 2. The Apron Diagram

the deep ecology movement. Supporters live in different cultures and have different religions. Furthermore, manifold kinds of consequences are derived from the platform because of these differences, because of differences in local conditions, and so on.

We must take four levels into account: (1) verbalized fundamental philosophical and religious ideas and intuitions; (2) the platform of the deep ecology movement; (3) more or less general consequences derived from the platform—lifestyles and general policies of every kind; and (4) concrete situations and practical decisions made in those situations.

The possibility of the platform principles being derived from a plurality of mutually inconsistent premises—the *B*-set and the *C*-set—is illustrated in the upper part of the apron diagram. *B* can be Buddhism, and *C* can be Christianity. *P* may be Spinoza's philosophy, or it could be Ecosophy

T. Similarly, the lower part of the diagram illustrates how, with one or more of the eight principles as part of a set of premises, mutually inconsistent conclusions may logically be derived, leading to the *C*-set or *B*-set of concrete decisions. *C* might be inspired by a sort of Christianity, and *B* by a sort of Buddhism. Or, again, P_1 may be Spinoza-inspired while P_2 follows a certain ecological philosophy. (Unfortunately, the relation of deepness in the apron diagram leads upward. If we are to avoid mixing metaphors, the apron should be turned upside down.)

The distinction between the four levels is important. Supporters of the deep ecology movement have ultimate views from which they derive their acceptance of the platform, but those views may be very different from person to person and from group to group. Likewise, supporters may disagree about what follows from the eight points, partly because they interpret them differently, partly because what follows does not follow from those eight points alone but from a wider set of premises, and these might be in conflict.

The deep ecology movement thus can be seen to manifest both plurality and unity: unity at level 2 (as is true for many global grassroots movements) and plurality at other levels. The apron diagram can be used to illustrate the same general aspects of other international movements, such as the social justice and peace movements.

Further Elaboration and Examples

1. Let us start by asking, What beliefs of supporters of the deep ecology movement might separate them from the rest of the supporters of the environmental movement? What might separate them on a fairly general and abstract level? No one answer is supposed to be the correct one, and the question itself may be interpreted in somewhat different ways.

Suppose one proposal contains eight points, each expressed through one, two, or three sentences. We are now going to study such a proposal from one and only one point of view, the premise-conclusion point of view.

2. We ask, How do supporters of the deep ecology movement justify their stated beliefs? Are some stated beliefs *based* on other beliefs they have? They cannot be based on other beliefs, because then you would have to have infinitely many. You must stop somewhere. Some are ultimate, at least temporarily ultimate. (Note that in speaking of beliefs we do not intend to

say that they are “*only* beliefs,” that is, that they are not certain or true or right or expressing facts.)

According to my experience, supporters of the deep ecology movement usually state beliefs on which they base some or all of their “eight-point beliefs.” These normally, but not always, have the character of ultimate beliefs, making them premises for their eight-point beliefs. That is, they suggest that from the former beliefs the eight-point beliefs follow as conclusions; thus, they accept the former beliefs as premises.

An example: Peter, a supporter of the deep ecology movement, says that all living beings have value in themselves. We ask him to justify that, if he does not think it is self-evident. Peter answers with two sentences: “Creatures that God has created all have a value in themselves. God created and creates every living kind of being.” We will say that Peter infers “All living beings have a value in themselves” as a conclusion from the two premises. He may then use the conclusion as a premise for new conclusions, for example: “Bacteria have value in themselves.” He only needs one more premise, namely, “Bacteria are living beings.” The new conclusion may again be used as one of the premises for reaching new conclusions. We get a *chain* of premise-conclusion relations.

We now introduce a distinction between “beliefs on level 1” and “beliefs on level 2.” Premises of the beliefs stated in the list of eight points we call beliefs on level 1, and the eight points themselves we call beliefs on level 2. Or speaking more generally: A set of beliefs that presents a proposal of what supporters of the deep ecology movement have *in common* on a fairly general and abstract level we call a set of beliefs on level 2. The premises of such a set, suggested by supporters of the deep ecology movement, we call beliefs on level 1.

In the example, the supporter of the deep ecology movement clearly has the existence of God as a creator as a premise. If he happens to have premises for his belief in God as a creator, we say that they also belong to level 1. That is, *any* premise Peter *uses* for his level-2 beliefs we class as belonging to his level-1 beliefs. We are not here interested in *what* they are, but that they are premises of the level-2 beliefs.

3. It turns out that different supporters of the deep ecology movement announce different level-1 beliefs—often incompatible sets. Or one sup-

porter does not understand at least some of the first-level beliefs of another supporter. To me a couple of Gary Snyder's Buddhist first-level beliefs, or rather some of his sentences expressing these beliefs, are ununderstandable. I might understand them if I studied Buddhism carefully enough, but such a study has no high priority: we agree on level 2.

The diversity of level-1 beliefs is a strength, not a weakness. There are no deep cultural differences without diversity at level 1.

Unity in diversity: unity at level 2, diversity at level 1!

4. Now we jump to a level we call level 4: practical decisions in concrete (dated) situations. "Ah, a moose in our garden. What do we do? Call the police!" Fifty years ago some people in Oslo ran for their guns. Now, (decent) people call the police, who are in charge of the practical decisions: shoot in earnest, shoot to tranquilize and transport the moose far out of Oslo, and so on. The decision to call the police may be taken by a supporter of the deep ecology movement, because he or she knows the rules and finds it is the best solution for the *moose*.

The level-4 decision cannot be based solely on level-2 beliefs. Critical, complex thinking involving a variety of beliefs intervenes. Those we say belong to level 3. Only under rare and special conditions do we try to articulate as fully as we can the additional premises leading from level 2 to level 4—"leading" in terms of a premise-conclusion chain. Difficult? In theory, yes, but we all sometimes use the aspects of premise and conclusion.

More or less inevitably, level 1 contains philosophical or religious beliefs (or both). I propose to characterize, or even define, a supporter of the deep ecology movement as a person whose environmentally relevant beliefs are based on philosophical or religious beliefs in the sense of having beliefs on level 1 that are, at least in a broad, *nonprofessional* sense, philosophical or religious.

The argumentation pattern of a supporter of the deep ecology movement, taken as a whole, reveals references to *ultimate premises*. This relates to the preferred sense of the term *deep*: the argumentation, if the supporter of the deep ecology movement tries to state what he or she ultimately stands for (in questions related to the environment and the ecological crisis), touches rock-bottom questions. Sheer deepness is not enough, however; the argumentation goes through level 2! James Watt, the U.S. administrator of

environmental policy under President Reagan, based his decisions on rock-bottom beliefs within his form of Christianity ("Why so much preservation when the end is near?"). He certainly did not accept any of the Naess-Sessions Eight Points or similar proposals.

A small technicality: some supporters of the deep ecology movement find that the intrinsic value of living beings is obvious, self-evident. Do we then say that they have no level-1 beliefs at this point? We may, but we may also say that the point belongs to *both* level 1 and level 2 for these particular supporters. Logically it is okay; they tell us that from premise *P*, the conclusion *P* follows. Anyhow, to hold that every living being has a value in itself is to enter the sphere of philosophical considerations. There are naturally a host of questions related to the four-level conception that lead us into difficulties, but here is not the place to go into them.

What, then, is the four-level conception good for? To sort out agreements and disagreements. For example, if by ecofeminism you mean that the ecological crisis owes essentially to the domination of masculine-type value priorities, this can be articulated on level 3. The strategy for overcoming the crisis, the level-4 decision, will be colored by a point of view belonging in deep ecology movement argumentation patterns. It shows up in the argumentation pattern of well-known deep ecology ecofeminists like Patsy Hallen (1987). Some supporters of the deep ecology movement will not entirely agree, and disagreement occurs between supporters of the deep ecology movement on levels 3 and 4.

The so-called apron diagram illustrates the kinds of room for agreement and disagreement. It is, however, not meant to suggest that only one definite set of level-2 beliefs should be available. Changing one or more of the eight points of the Naess-Sessions proposal means that changes will follow on the other levels. A movement is dynamic and manifests changes of emphasis.

Two things are often forgotten: the apron serves to clarify the specific character of a subspecies of the environmental movement. In a subspecies characterization, one does not include characteristics of the species as a whole. Supporters of the shallow or reform movement tend to argue only on levels 3 and 4, that is, their argumentation pattern when described in terms of the apron is wholly contained at those levels.

Against the term *shallow* the reformists argue that going into philoso-

The Apron Diagram

phy, questions about intrinsic value, meaning of life, and so on, is side-tracking the issue, getting lost in a blind alley, plus it undermines realistic cost-benefit analysis. It is therefore a plus, not a minus, to limit oneself to levels 3 and 4.

The second thing easily forgotten is the fact that the apron consistently limits itself to premise-conclusion relations; this arrangement is only one among many others, the “genetic” arrangements.

The Basics of Deep Ecology

I am very grateful to be here. Some weeks ago when I thought of this occasion I had two feelings. The first was that I was going to visit the British aristocracy! In school we learned a lot about the British aristocracy, and mostly it was positive. We got the notion that they were the best. By aristocracy I mean those who are in the forefront, the most enlightened and far-seeing members of society. I have a feeling that I am going to taste this British aristocracy today!

The second feeling was that I had come from one occupied country to another occupied country. The people of Norway were occupied from 1940 to 1945 by very unkind people. Now I feel that we are occupied by kind and well-meaning people. They do things for our welfare but in reality we feel completely estranged from the essence of the good life. I am sure that the same is true in Britain today. Only, I am glad to say, you were not occupied by bad people.

Those who occupy my country talk about the useless hills. Only a couple of days ago they referred to the useless hills in the neighborhood of Oslo, which, they thought, should be developed as a site for mansions. People who already have very nice houses could then go up to the hills and have still nicer houses by cutting down all the trees. So we are very far from a green and free society.

The realization of any society worthy of the name green presupposes that policies characteristic of deep ecology are adopted. The clarification of

A summary of the 1987 Schumacher lecture, this article was reprinted with permission from *Resurgence* (1988). It also appeared in *The Green Fuse: The Schumacher Lectures*, edited by John Button (London: Quartet Books 1990), 130–37.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

the term *deep ecology* will, I hope, contribute in a modest way to the realization of our aims. I am engaged in the articulation of the fundamental positions that are presupposed in green societies.

People ask, "Why can't we just feel and not articulate?" My answer is this: In our society there is constant communication, and we must be able to communicate on a verbal plane. If we are able to articulate our basic goals in life and get our opponents to agree to them, then we can go on to discuss practical matters such as "We must have more parking space." When we agree on basic goals we can ask, All right, what's the relation between our basic goals in life and this parking place? So, the articulation of our basic goals has an important role. We should never engage in any discussion on technicalities without asking, What do we basically need in life? Always ask the basic question. This is what I mean by the term *deep ecology movement*, or typical of supporters of it.

Let me then list some key sentences commonly held to be characteristic of a green society. It should be decentralized and should be a grassroots democracy. There should be social responsibility, mutual aid, and a reign of nonviolence. People should live in voluntary simplicity, with a high degree of self-reliance and with moderate mobility. Different generations should be able to live together and work together. There should be a feeling of community; technology should be appropriate; industrial and agricultural units should be small. Home and place of work should be near each other and transportation mainly public. There should be an absence of social hierarchy and an absence of male domination.

You will have noticed that all these concepts lack any kind of reference to nature or to ecology, but they are, of course, basic to a vision of a green society.

Then there are concepts of another type, namely, respect for nature, reverence for life, ecological agriculture, absence of monoculture forests, absence of animal factories, free access to nature, and so on.

Then there is a third aspect of the deep ecology approach. This is characterized by our deep relationship with the environment and a joyful acceptance of this relationship. It is taken for granted that the self is basically ecological. Talk about human beings in the environment is misleading, for we are as much out there as inside here. The beauty of a tree is as much in the tree as it is inside us. There is an object, a medium, and a subject, but

you cannot separate these three except as abstractions. People with this approach think in these terms: world first, men not apart, friends of the earth, ecological responsibility, the forest for the trees, hug the trees. If we say “the forest for the trees” we acknowledge that a forest is an end in itself; it does not need to serve any narrow human purpose.

The terms I have mentioned fall into three classes: those solely concerned with human society, those that combine society with nature, and those solely concerned with nature. Some groups working for the realization of a green society prefer the first class of slogans; others use the second or the third class.

There is an interesting difference between thinking green in central and Mediterranean Europe and thinking green in the marginal lands of north and south. By marginal northern and southern lands I mean Scandinavia, Great Britain, Canada, the northwestern United States, and Australia. I call them the “natural greens.” Then there are the “social greens” in Germany, France, the Mediterranean, and many other places where more stress is put upon society. The social greens say that a wrong attitude to nature reflects a wrong attitude between people. Domination, exploitation, and lack of respect within a society result in the same attitude to nature. They assume that if you get rid of these bad attitudes within society, then, more or less automatically, your relation to nature will be okay. What you have to do is reform society. You have to get involved in politics. Don’t disappear into the wilderness and live in a nice community as if this could be the norm of the whole society.

The natural greens say, “What’s so exciting about people when you consider porcupines or whales? We have to reduce the human population and have a nice planet.” That’s a caricature of them, but there’s a tendency to speak as if people were superfluous.

The supporters of the deep ecology movement combine the social greens with the natural greens while avoiding the extremes of both.

Some people have a concept of a green society that is utopian. They put into the term *green society* everything that is perfect. Others point out that Green party programs cannot just be descriptions of utopia. They must serve as blueprints for a major transition toward a green society. Fundamentalists say exactly how things should be while realists stress that in politics you have to use tactical considerations; a Green party cannot act in a utopian way.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

In discussions between fundamentalists and realists we should adopt the Gandhian form of nonviolence. In this you see the point of your opponent, you listen to the argument, interpreting benevolently, as far as you can. The Latin phrase is *Stupiditas adversariorum non est praeter necessitatem argumenendam*. That means you shouldn't make your opponent look unnecessarily stupid. During the 1960s we had a lot of different groups on the left. There was richness and variety, but they were fighting each other. Then came the ecology movement and from the very start there was a difference. There was much less of violent polemics. If your communication is consistently positive, you will get down deeper into the issues. If you say, "Wrong. You are absolutely wrong," your opponents will stick to their argument and say, "No, I was not wrong," but if you say, "Maybe you could put it a little differently," then you may be able to get agreement, and if you really disagree, you will be able to clarify it.

The supporters of the deep ecology movement are all over the world. A small minority are from the universities, a tiny fraction are writing about these matters, but our real strength is with those who don't give lectures but who are supporting the deep ecology movement in their lives. This movement started in the early 1960s with people like Rachel Carson. Those people were not speaking of cancer or of polluted air just because it was bad for humanity. They said, "It cannot be done to the planet, it cannot be done to nature, it cannot be done to the animals. It simply cannot be done." Those pioneers had a vision of reality that does not allow us to trample on natural life. Theirs was not a moral impulse—and I have the feeling that moralizing is not a great force in this world. So the ethics and the morals of environmentalism are of secondary importance. What is important is to get people to see reality and our relation to nature.

I introduced the distinction between "shallow" ecology and "deep" ecology. The supporters of shallow ecology think that reforming human relations toward nature can be done within the existing structure of society. They propose to make small changes here and there within the institutions; they suggest technical development to reduce pollution. They don't get down to the basics because they think that business can continue as usual. They will give a little more money to the department of the environment and to research. However, research only postpones the problem. There's a politician here in Great Britain who says that we must have more research

on the causes of acid rain. The better the researcher is, the more he or she says, “Oh, we don’t know enough, we must have more money.” Research is now on the wrong side. Researchers get one year to come up with some answers, but at the end of the year they say, “Well, we’re just starting, it seems to be very complicated. We need more time and money.” That’s how endless research goes on.

The deep ecology movement will say that we can never know enough—*docta ignorantia*, conscious ignorance. The best field ecologists use their intuition about reality. They can, of course, find out a little here and there, but they cannot always know the long-range effects of human interference. They understand the enormous complexity of the planet and of ourselves. So from this *docta ignorantia*, we get the idea that it is better not to do anything in which great risks are involved. The politician, however, is here to do things. So either you say any action that may damage the planet is wrong and we cannot do it, or you say we cannot know whether it is wrong or right and therefore we must not do it.

The tendency of the supporters of shallow ecology is to avoid the basic questions, whereas the deep ecology movement concerns itself with basic beliefs and assumptions about the universe. If you articulate the principles of the deep ecology movement you get a total view. The term *total view* is essential. The deep ecology movement is a total view. It covers our basic assumptions, our life philosophy, and our decisions in everyday life. I have also called the total view an “ecosophy” in order to distinguish it from ecology as a science. *Sophia* is Greek for wisdom. So, ecosophy means eco-wisdom, and wisdom has always been related to practice.

When we in the deep ecology movement talk about pollution, we ask, Pollution for whom? There are so many living beings. Are you talking about pollution for human beings? What about pollution for others? When we talk about resources, we ask, What about resources for squirrels as well as resources for human beings? When we talk about pollution, we must also consider the optimum population of rats. I think we have to avoid feeding rats as much as we do. We always go from discussing the sphere of human life, which is important for us, to life in general. Moreover, we would say that any short-range solution should cover at least the next fifty years. In deep ecology, fifty years is a very short time. In contrast to this is the shorthand solution—that is, next year, next election.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

In the deep ecology movement we are biocentric or ecocentric. For us it is the ecosphere, the whole planet, Gaia, that is the basic unit, and every living being has an intrinsic value.

The supporters of the deep ecology movement agree upon this, but in their very basic views about the universe and themselves, they may well disagree. They may have, for example, a Buddhist-inspired philosophy, or a Christian-inspired philosophy, or a nonreligious approach. At this most basic level we cannot understand each other. We cannot understand five or ten different religions. We shouldn't pretend to. It is culturally disastrous to pretend that we can understand all religions or all philosophies. That is a terrible error on the part of the universities—there are courses in all philosophies and all religions of the world, and the students are supposed to understand philosophers who are miles apart. I feel it is important in the deep ecology movement to have plurality, especially at this deepest level. However, from all religions and philosophical approaches we agree on the following points (comments are in parentheses).

1. The well-being and flourishing of human and nonhuman life on earth have intrinsic value, inherent worth. This value is independent of the usefulness of the nonhuman world for narrow human purposes.

2. Richness and diversity of life-forms contribute to a realization of these values and are also values in themselves. (Richness means we have to have an abundance of life of all kinds. We have to replenish the earth. In this sense, landscapes are living beings and so are rivers. I can't and I don't have to justify that diversity and richness; plurality of life is good in itself. People who claim to be realistic say, Well, I keep to facts. What, though, is the status of this sentence: *So-and-so is a fact*? In logic you need rules, and the goodness of those rules cannot be shown—they cannot be argued, they cannot come as a conclusion. If you say, "This rule of logic is valid," then I say, "Well, show me that, prove it." You have to use premises to arrive at a conclusion, and to do that, you have to have rules of inference by which you come from the premise to the conclusion. You cannot start by saying "I am for facts," because the term *fact* itself is a tremendously complex affair. Aristotle said that to try to prove everything is a sign of bad education. Diversity of life for us is such a premise; we don't need to waste time proving it.)

3. Human beings have no right to reduce this richness and diversity except to satisfy vital needs. (People say to me, "Oh, but what do you mean by

right?” I say, “I mean exactly the same as when children say, You have no right to hit my little sister”—and this is established practice among children, so there must be something in it.)

4. The flourishing of human life and culture is compatible with a substantial decrease of the human population. Flourishing of nonhuman life requires such a decrease. (Some people would call this “antihuman,” but I believe that it is not good even for human beings that we number five thousand million and are soon going to be eight thousand million. It’s not good even for the deep cultural differences on earth; it’s very difficult to have cultural differences with no space in between. This significant decrease in human population will not happen overnight. It may take a thousand years. This is our long-range vision. People say, A thousand years has nothing to do with the problem of today. Yes, it does have to do with today. For example, we have to change our architecture. Old people need small children around because small children are, after all, important. So the architecture will have to be such that there is a common ground, without streets, where small children and old people can get together. If we have two children per couple on an average, then there will be a transition period of hundreds of years but eventually we will have a smaller population.)

5. Present-day human interference with the nonhuman world is excessive, and the situation is rapidly worsening.

6. Policies must therefore be changed. These policies will affect our basic economic, technological, and ideological structures. (I have not had the courage to go into detail and define what these different structures will be because we are going to have a lot of different green societies. We shouldn’t have one set of structures imposed.)

7. The change in our attitudes will bring an appreciation of the quality of life rather than adherence to an increasingly higher standard of living. There will be a profound awareness of the difference between big and great. (We will have a great society with no bigness. I am very much in love with the term *quality of life*. People say, “Well, that’s just a slogan. Standard of living is quantitative—that we can discuss and understand—but *quality of life*, what’s that?” I am very much for the richness and luxury that I have in my cottage in the high mountains of Norway. For more than ten years of living there, the feeling of richness has been tremendous. This is quality of life, however, not standard of living. If there is snow in winter, I dig down

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

into a lake for water. To heat that water from -1° to $+1^{\circ}$ takes as many calories as to heat it from $+1^{\circ}$ to 100° . So I use cold water for washing, but after one or two months of living there I feel very comfortable.)

In Great Britain and in Norway we have to accept a drop in our standard of living in order to have a standard that is universalizable. What I am saying is take it easy, take it easy; life quality may still be there, but you will have to shed some of your bad habits that destroy the planet. Much of the high standard of living is sheer bad habits that we cannot sustain because they are ruining the balance of Gaia.

8. Those who subscribe to the foregoing points have an obligation directly or indirectly to try to implement necessary changes.

The Breadth and the Limits of the Deep Ecology Movement

The gist of what I say here may be expressed in three sentences: To be joyfully active in the deep ecology movement is a serious affair. It is ethically unobjectionable not to combine that involvement with being active in the peace movement and the social justice movement. We respect our partners in the Green movement but have “more than enough!” to do where we stand.

It is a never-ending joy to think of the existence of a broad movement to protect the wild and free from thoughtless interference by human beings. It is a special joy to see how many people primarily occupied with mere survival nevertheless try to protect locally what is left of free nature. Defenders of free nature are, of course, always in a minority, but to be aware of comrades in arms locally and in so many countries helps to reduce the feelings of sorrow that can easily take hold when we contemplate the reigning passivity in the face of the ecological crisis.

I shall never forget traveling in 1949 through India and Pakistan to a mountain bordering Afghanistan. Because of our lack of money and the five hundred pounds of equipment and food, we inevitably came in close contact with people who were very poor from the point of view of the West. They were eager to hear what made us leave our country on a kind of pilgrimage. Again and again, it astonished us to see how well they understood our longings, and it was touching to hear them often say “How I would like to be with you.” Through more than twenty-five hundred years, their culture had embraced a respect for the dignity and wisdom of mountains and the living beings roaming the (at that time) enormous Himalayan forests.

This article was reprinted with permission from *Wild Earth* (Spring 1993): 74–75.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

Of course, all they could do was, together with other activists, protect the patches of free nature in their own neighborhood.

How do people in materially poor countries react when we talk about deep ecology? Using words common in their own cultures, many say "But this is what I always have felt!" This is not a majority reaction, but a minority that I guess is no smaller than in the so-called rich countries. Some are glad to get words for what they feel.

People who have never heard the term are supporting the deep ecology movement. Most supporters would feel bored if I, as a theoretician, started conceptual clarification of details. Yet, their efforts are consistent with deep ecology and often restrain the galloping destruction in their neighborhoods. It is a strange belief that people who work hard to survive are somehow unable to feel the majesty of mountains, the inherent value of forests and wildlife. Yet, many people believe that they are more "anthropocentric" than we are in the technocratic West.

In short, it is encouraging to experience the vast, intercultural roots of deep ecology attitudes and to see that they are alive among people who focus on procuring life's necessities. The deep ecology movement is broader than sometimes suggested. The broadness shows itself in the variety of scenarios for a better future envisaged by the supporters. Human cultural diversity is part of the richness of life-forms on Earth. Many supporters do not seem worried about the prospect of fairly uniform green societies all over the globe, but as I see it, ecological sustainability as an absolute requirement does not limit social-political structure to a single culture.

The peace movement, the social justice movement, and the radical environmental movement are the three movements in which work at the grass-roots level by hundreds of thousands of people is indispensable and has considerable influence in world affairs. Within the radical environmental movement, I include not only the deep ecology movement but also highly engaged "radical" supporters of more anthropocentric views who have the same serious view of the ecological crisis as the supporters of the deep ecology movement. Each of the movements introduces limitations on the range of cultures. The requirements of the three overlap but are not identical.

The tremendous upsurge of environmental concern since the 1960s has caused many supporters of the peace and social justice movements to jump on the environmental bandwagon, but all three movements constantly

need reinforcements. Because they are dynamic social movements, exact delimitation of the three is, of course, out of the question; historically, though, much can be said about what has happened since the Second World War in terms of those three.

In the 1950s, when Third World problematics gained force (with, for example, "Trade, not aid" as a slogan), there was considerable pressure to combine the peace and social justice movements into one. Some activists supporting this combination saw social injustice as a sort of violence, *structural* violence. The nonviolent battle against large-scale violence then comprised both the "classical" peace movement and a large part of the social justice movement. (Johan Galtung's works are central to this trend.) It has turned out, however, that people inspired by the vision of a world without wars had more than enough work to do without direct participation in the complexities of how to fight social injustice, even though activism against maldistribution and imperialism and other forms of obstructing self-realization potential over vast areas can be compatible with keeping peace. On the other hand, active involvement in typical social justice conflicts may require all of one's energy and leave no time for activism in matters of peace. The division of labor, however, does result in underestimation of the work of our friends in the other movements.

In recent decades millions of very poor people in Southeast Asia have seen their standard of living significantly bettered. How can we but rejoice? Yet, interference with ecosystems has concurrently increased. The prospect of a billion or more people being rescued from severe need does not necessarily mean a gain in overcoming the ecological crisis. Leaders of social democratic regimes often talk as if development were part of the (smooth) way of overcoming the crisis. This talk is politically convenient but utterly misleading.

The empowerment of people in the West living in a most degrading way in the midst of an opulence never equaled in world history (read "in human recorded history of human societies") is an imperative, and more people are needed to try to change those shameful conditions. Some supporters of the deep ecology movement may feel they ought to join, and that may be the right thing for them to do. They know, though, that the fight against the ecological crisis will still need as many activists even if the shameful conditions are eliminated.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

The very ambitious aim of the Green movement as conceived in Europe in the late 1960s is to reach the goals of all three great grassroots movements: no wars, social justice, and full ecological sustainability. When students voted overwhelmingly in the first green wave, they were led by former anarchists, Marxists, and peace activists. The Green movement is supposed to avoid one-sidedness and sectarianism, letting the three movements blossom in constant close collaboration.

Collaboration does not imply extensive reading of all pertinent literature and keeping informed about details of what is going on in the other two movements. That tends to feed depression and despair. Reading is passive, and the information from all over the world is mostly discouraging. Perhaps I say this because of my experience of living under Nazi occupation from 1941 to 1945, but a persistent question is, How about morale? Can anything be done to keep it (the fighting spirit) at its highest level?

In sum, let us do our job as well as we can and rejoice that others do theirs, keeping in touch and sometimes acting together. This is the surest way to keep the spirit.

The Deep Ecology Movement: Some Philosophical Aspects

Deep Ecology on the Defensive

Increasing pressures for growth have forced the vast majority of ecologists and other environmental professionals into a defensive position. let me illustrate.

The field ecologist K, who both professionally and personally vigorously advocated deep ecological principles in the late 1960s, encountered considerable resistance. Colleagues at the university said that he should keep to his science and not meddle in philosophical and political matters, that he should resist the temptation to become a prominent “popularizer” through exposure in the mass media. Nevertheless, he continued and influenced thousands (including myself). He became a recognized “expert” in assessing the damage done when bears killed or maimed sheep or other domestic animals in Norway. According to the law, their owners are to be paid damages. Licensed hunters can get permission to shoot a bear if its misdeeds become considerable.¹ Growth pressures required consolidating the sheep industry, and sheep owners became fewer, richer, and more prone to live in towns. Because of wage increases, they could not afford to hire shepherds to watch their flocks, so the sheep were left alone in what were traditionally “bear territories.” In spite of this invasion, bear populations grew, and troubles multiplied.

What was K’s reaction? Did he set limits to human encroachments on

This article was reprinted with permission from *Philosophical Inquiry* 8 (1986): 10–31.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

bear territory? Did he directly apply his deep ecology perspective? Quite the contrary. He adopted a shallow wildlife management perspective that defended the sheep owners: more money in compensation for losses, quicker compensation, and immediate hiring of hunters to reduce the bear population. Other deep ecology supporters noted with concern his altered public "image"; had K really abandoned his former value priorities? Privately he insisted that he had not, but in public he was silent.

The reason for K's unexpected actions was not difficult to find: the force of economic growth was so strong that the laws protecting bears would be changed in a direction highly unfavorable to the bears if the sheep owners were not soon pacified by having some of their demands met. Moreover, some of their demands seemed reasonable. After all, it did cost a lot of money to hire and equip rescuers to locate a flock of sheep that had been harassed by a bear and, further, to prove the bear's guilt. In addition, the bureaucratic procedures involved were time-consuming. In short, K had not changed his basic value priorities at all. Rather, he had adopted a purely defensive compromise. He stopped promoting his deep ecology philosophy in public to retain credibility and standing among opponents of his principles.

What is true of K is true of thousands more. These people often hold responsible positions from which they might strengthen responsible environmental policy. Given the exponential forces of growth, however, their publications are limited to narrowly professional and specialized concerns. Their writings are surely competent but lack a deeper, more comprehensive perspective (although I admit that there are some brilliant exceptions). If professional ecologists persist in voicing their value priorities, their jobs are often imperiled, or they tend to lose influence and status among those who are in charge of general policies. Privately, they may admit the necessity for deep and far-reaching changes, but they remain silent in public. As a result, their positive impact on the public has largely vanished. Deeply concerned people feel abandoned by the "experts."

In ecological debate many participants know a great deal about particular conservation policies in particular places, and many others have strong opinions regarding fundamental philosophical questions of environmental ethics, but only a few have both qualities. When they are silent, the loss is formidable.

Let me illustrate again. A family of four decides to acquire four chairs for a small room, newly added to the home. They buy the chairs and all have peace of mind. Then one of them gets an urge to put ten more chairs in the room. Two of the family members who are technically talented and eager to satisfy any “need” use their time to solve the sophisticated physical and mathematical problems involved. When they ask the fourth member to work overtime to get the money to purchase the ten chairs, she answers that the chairs are unnecessary for a life rich in intrinsic values and simple in means. She begins to argue for her view, but the two technocrats insist that first she should work through all the alternative solutions to the Ten Chair problem. At last, she wonderfully simplifies the argument. If the ten chairs are not a desired end, it is pointless to discuss the means by which this might be achieved. The technically talented find other outlets for their surplus energy, for there are always enough legitimate problems to work on.

The complicated question of how industrial societies can increase energy production with the least undesirable consequences is of the same kind: a waste of time if the increase is pointless in relation to ultimate ends. When thousands of experts hired by government and other big institutions devote their time to this complicated problem, it is difficult for the public to learn that many of them judge the problem pointless and irrelevant. What is relevant, according to them, are the problems of how to stabilize and eventually decrease consumption without loss of life quality.

A Call to Speak Out

What I advocate and argue for is this: even those who completely subsume ecological policies under the narrow ends of human health and well-being cannot attain their more modest aims, at least not fully and easily, without being joined by supporters of deep ecology. They need what these people have to contribute, as this alliance will work for them more often than it works against them. Those in charge of environmental policies, even if they are resource-oriented (and growth-tolerating?) decision makers, will increasingly welcome what deep ecology supporters have to say, if only for

tactical and not fundamental reasons. Even though the more radical ethic may seem nonsensical or untenable to them, they know that its advocates are doing in practice conservation work that sooner or later must be done. They concur with the practice, although they operate from diverging theories. If I am right, the time is ripe for professional followers of deep ecology to break their silence and freely express their deepest concerns. A bolder advocacy of deep ecology by those who are working within the shallow, resource-oriented "environmental" sphere is the best strategy for reestablishing some of the strength of this movement among the general public and thereby contributing, however modestly, to a turning of the tide.

What do I mean by saying that even the more modest aims of shallow environmentalism have a need for deep ecology? We can see this by considering the *World Conservation Strategy* prepared by the International Union for Conservation of Nature and Natural Resources (IUCN) with the advice, cooperation, and financial assistance of the United Nations Environmental Program (UNEP) and the World Wildlife Fund (WWF). The argument in this important publication is through and through anthropocentric in the sense that all its recommendations are justified in terms of their effects on human health and well-being. Even the recommended environmental ethic, with its attendant environmental education campaign, has human beings in harmony with nature for human good. "A new ethic, embracing plants and animals as well as people, is required for human societies to live in harmony with the natural world on which they depend for survival and well-being" (IUCN 1980: sec. 13). Such an ethic would surely be more effective if it were acted upon by people who believe in its validity, rather than by those who merely believe in its usefulness. This, I think, will come to be understood more and more by those in charge of educational policies. Quite simply, it is indecent for a teacher to proclaim an ethic only for tactical reasons. Further, this point applies to all aspects of world conservation strategy. Conservation strategy will be more eagerly implemented by people who love what they are conserving, and who are convinced that what they love is intrinsically lovable. Such lovers will not want to hide their attitudes and values, but rather will increasingly give voice to them in public. They have a genuine ethics of conservation, not merely a tactically useful instrument for social and political ends.

In short, environmental education campaigns can fortunately combine anthropocentric arguments with a practical land and sea ethic based on a deeper and more fundamental naturalistic philosophical or religious perspective, and on a set of norms resting on intrinsic values. The inherent strength of this overall position will be lost, however, if those who work professionally on environmental problems do not give public testimony to these fundamental norms.

This article is hortatory, in the positive etymological sense of that word. I seek “to urge, incite, instigate, encourage, cheer” (Latin: *hortari*). This may seem unacademic in a philosophical journal, but I consider it justifiable because of an intimate relationship between hortatory sentences and basic philosophical views, which I will formulate below.

What Is Deep Ecology?

So far, I have used the term *deep ecology movement* without trying to define it. One should not expect much from definitions of movements—think of terms such as *conservatism*, *liberalism*, and *feminism*. Moreover, it is not necessary that supporters adhere to exactly the same definition. In what follows, a set of principles, or key terms and phrases, agreed upon by George Sessions and myself, are tentatively proposed as basic to deep ecology.² The list is followed by comments on each of the eight principles.

1. The well-being and flourishing of human and nonhuman life on Earth have value in themselves (synonyms: intrinsic value, inherent value). These values are independent of the usefulness of the nonhuman world for human purposes.
2. Richness and diversity of life-forms contribute to the relation of these values and are also values in themselves.
3. Human beings have no right to reduce this richness and diversity except to satisfy vital needs.
4. The flourishing of human life and cultures is compatible with a substantial decrease of the human population. The flourishing of nonhuman life requires such a decrease.
5. Current human interference with the nonhuman world is excessive, and the situation is rapidly worsening.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

6. Policies must therefore be changed. These policies affect basic economic, technological, and ideological structures. The resulting state of affairs will be deeply different from the present state of affairs.
7. The ideological change is mainly that of appreciating life quality (dwelling in situations of inherent value) rather than adhering to an increasingly higher standard of living. There will be a profound awareness of the difference between big and great.
8. Those who subscribe to the foregoing points have an obligation directly or indirectly to try to implement the necessary changes. It is this principle that highlights the importance of *deep questioning* as the process by which to follow/develop/enact the other principles.

Basic Principle 1

Formulation 1 refers to the biosphere or, more accurately, to the eco-sphere as a whole. This includes individuals, species, populations, and habitats, as well as human and nonhuman cultures. From our current knowledge of all-pervasive intimate relationships, this implies a fundamental deep concern and respect. Ecological processes on the planet should, on the whole, remain intact. “The world environment should remain ‘natural’” (Gary Snyder).

The term *life* is used here in a comprehensive, nontechnical way to refer also to what biologists classify as “nonliving”: rivers (watersheds), landscapes, ecosystems. For supporters of deep ecology, slogans such as “Let the river live” illustrate this broader usage so common in most cultures.

Inherent value, as used in formulation 1, is common in deep ecology literature. “The presence of inherent value in a natural object is independent of any awareness, interest, or appreciation of it by any conscious being” (Regan 1981: 30).

Basic Principle 2

More technically, formulation 2 concerns diversity and complexity. From an ecological standpoint, complexity and symbiosis are conditions for maximizing diversity. So-called simple, lower, or primitive species of plants and animals contribute essentially to richness and diversity of life.

They have value in themselves and are not merely steps toward the so-called higher or rational life-forms. The second principle presupposes that life itself, as a process over evolutionary time, implies an increase of diversity and richness. The refusal to acknowledge that some life-forms have greater or lesser intrinsic value than others (see points 1 and 2) runs counter to the formulations of some ecological philosophers and New Age writers.

Complexity, as referred to here, is different from complication. Urban life may be more complicated than life in a natural setting without being more complex in the sense of multifaceted quality.

Basic Principle 3

The term *vital need* is left deliberately vague in formulation 3 to allow for considerable latitude in judgment. Differences in climate and related factors, together with differences in the structures of societies as they now exist, need to be considered. (For some Eskimos, snowmobiles are necessary today to satisfy vital needs; the same cannot be said for tourists.)

Basic Principle 4

People in the materially richest countries cannot be expected to reduce their excessive interference with the nonhuman world to a moderate level overnight. The stabilization and reduction of the human population will take time. Interim strategies need to be developed. In no way, however, does this excuse the current complacency. The extreme seriousness of our situation must first be realized, and the longer we wait the more drastic will be the measures needed. Until deep changes are made, substantial decreases in richness and diversity are liable to occur: the rate of extinction of species will be ten to one hundred times greater than at any other period in Earth's history.

Basic Principle 5

Formulation 5 is mild. For a realistic assessment of the situation, see the unabridged version of the IUCN's *World Conservation Strategy*. There are

other works to be highly recommended, such as Gerald Barney's *Global 2000 Report to the President of the United States*.

The slogan of "noninterference" does not imply that human beings should not modify some ecosystems as do other species. Human beings have modified the earth and will probably continue to do so. At issue is the nature and extent of such interference.

The fight to preserve and extend areas of wilderness or near-wilderness should continue and should focus on the general ecological functions of these areas. One such function is that large wilderness areas are required in the biosphere to allow for continued evolutionary speciation of animals and plants. Most currently designated wilderness areas and game preserves are not large enough to allow for such speciation.

Basic Principle 6

Economic growth as conceived and implemented today by the industrial states is incompatible with principles 1–5. There is only a faint resemblance between ideal sustainable forms of economic growth and current policies of the industrial societies. Moreover, "sustainable" still means "sustainable in relation to people."

Present-day ideology tends to value things because they are scarce and because they have a commodity value. There is prestige in vast consumption and waste (to mention only several relevant factors).

Whereas "self-determination," "local community," and "think globally, act locally" will remain key terms in the ecology of human societies, nevertheless the implementation of deep changes requires increasingly global action, action across borders.

Governments in Third World countries are mostly uninterested in deep ecological issues. When the governments of industrial societies try to promote ecological measures through Third World governments, practically nothing is accomplished (for example, with problems of desertification). Given this situation, support for global action through nongovernmental international organizations becomes increasingly important. Many of these organizations are able to act globally "from grass roots to grass roots," thus avoiding negative governmental interference.

Cultural diversity today requires advanced technology, that is, techniques that advance the basic goals of each culture. So-called soft, intermediate, and alternative technologies are steps in this direction.

Basic Principle 7

Some economists criticize the term *quality of life* because, they say, it is vague. On closer inspection, however, what they consider to be vagueness is actually the nonquantitative nature of the term. One cannot quantify adequately what is important for quality of life as discussed here, and there is no need to do so.

Basic Principle 8

There is ample room for different opinions about *priorities*: what should be done first, what next; what is most urgent; what is clearly necessary as opposed to highly desirable but not absolutely pressing.

Although many supporters of the deep ecology movement may find the above formulations useful, others will certainly feel that they are imperfect, even misleading. If they need to formulate in a few words what is basic in deep ecology, they will propose an alternative set of sentences. I shall, of course, be glad to refer to those formulations as alternatives. There ought to be a measure of diversity in what is considered basic and common.

Should we call the movement the deep ecology movement?³ There are at least six other designations that cover most of the same issues: "Ecological Resistance," used by John Rodman in important discussions; "The New Natural Philosophy," coined by Joseph Meeker; "Eco-philosophy," used by Sigmund Kvaloy and others to emphasize (1) a highly critical assessment of industrial growth societies from a general ecological point of view and (2) the ecology of the human species; "Green Philosophy and Politics" (although the term *green* is often used in Europe, in the United States it has a misleading association with the rather "blue" Green Revolution); "Sustainable Earth Ethics," as used by G. Tyler Miller; and "Ecos-

ophy,” eco-wisdom, which is my own favorite term. Others could also be mentioned.

Why use the adjective *deep*? This question will be easier to answer after the contrast is made between shallow and deep ecological concerns.

What I am talking about is not a philosophy in any academic sense, nor is it institutionalized as a religion or an ideology. Various persons come together in campaigns and direct actions. They form a circle of friends supporting the same kind of lifestyle, which others term “simple” but they themselves think is rich and many-sided. They agree on a vast array of political issues, although they may otherwise support different political parties. As in all social movements, slogans and rhetoric are indispensable for ingroup coherence. They react together against the same threats in a predominantly nonviolent way. Perhaps the most influential participants are artists and writers who do not articulate their insights in terms of professional philosophy, but do express themselves in art or poetry. For these reasons, I use the term *movement* rather than *philosophy*.

Deep Versus Shallow Ecology

A number of key terms and slogans from the environmental debate will clarify the contrast between the shallow and the deep ecology movements.

Pollution

Shallow approach: Technology seeks to purify the air and water and to spread pollution more evenly. Laws limit permissible pollution. Polluting industries are preferably exported to developing countries.

Deep approach: Pollution is evaluated from a biospheric point of view,⁴ not centering on its effects on human health, but on life as a whole, including life conditions of every species and system. The shallow reaction to acid rain is to avoid action by demands for more research, demands to find species of trees tolerating high acidity, and so on, whereas the deep approach concentrates on what is going on in the total ecosystem and asks for a high-priority fight against the economy and technology responsible for acid rain.

The priority is to fight deep causes of pollution, not merely the super-

ficial, short-range effects. The Third and Fourth worlds cannot afford to pay the total cost of the war against pollution in their regions, and consequently they require the assistance of the First and Second worlds. Exporting pollution is not only a crime against humanity, but also against life.

Resources

Shallow approach: The emphasis is on resources for human beings, especially the present generation in affluent societies. In this view, the Earth's resources belong to those who have the technology to exploit them. There is confidence that resources will not be depleted because, as they get rarer, a high market price will conserve them, and substitutes will be found through technological progress. Further, animals, plants, and natural objects are valuable only as resources for human beings. If no human use is known, they can be destroyed with indifference.

Deep approach: The concern here is with resources and habitat for all life-forms for their own sake. No natural object is conceived of solely as a resource. This then leads to a critical evaluation of human modes of production and consumption. One must ask, To what extent does an increase here favor ultimate values in human life? To what extent does it satisfy vital needs, locally and globally? How can economic, legal, and educational institutions be changed to counteract destructive increases? How can resource use serve the quality of life rather than the economic standard of living as generally promoted in consumerism? There is an emphasis here on an *ecosystem approach* rather than just the consideration of isolated life-forms or local situations. There is a long-range maximal perspective of time and place.

Population

Shallow approach: The threat of (human) overpopulation is seen mainly as a problem for developing countries. One condones or even cheers population increases in one's own country for shortsighted economic, military, or other reasons; an increase in the number of human beings is considered a value in itself or as economically profitable. The issue of optimum population for humankind is discussed without reference to the question of the

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

optimum population of other life-forms. The destruction of wild habitats caused by an increasing human population is accepted as an inevitable evil. Drastic decreases of wild life-forms tend to be accepted as long as species are not driven to extinction. Animal social relations are ignored. The long-term substantial reduction of the global human population is not seen as a desired goal. One has a right to defend one's own borders against "illegal aliens," no matter what the population pressures elsewhere.

Deep approach: It is recognized that excessive pressures on planetary life conditions stem from the human population explosion. The pressure stemming from industrial societies is a major factor, and population reduction must have a high priority in those societies, as well as in developing countries. Estimates of an optimal human population vary. Some quantitative estimates are 100 million, 500 million, and 1,000 million, but it is recognized that there must be a long-range human-population reduction through mild but tenacious political and economic measures. This will make possible, as a result of increased habitat, population growth for thousands of species that are now constrained by human pressures.

Cultural Diversity and Appropriate Technology

Shallow approach: Industrialization of the kind manifested in the West is held to be the goal for developing countries. The universal adoption of Western technology is compatible with mild cultural diversity and the conservation of good (from the Western point of view) elements in present-day nonindustrial societies. There is a low estimate of deep cultural differences that deviate significantly from Western standards.

Deep approach: Cultural diversity is an analogue on the human level to the biological richness and diversity of life-forms. We should give high priority to cultural anthropology in education in industrial societies. We should limit the impact of Western technology on nonindustrial countries and defend the Fourth World against foreign domination. Political and economic policies should favor subcultures within industrialized societies. Local, soft technologies will allow a basic cultural assessment of any technical innovations. The deep approach freely criticizes so-called advanced technology and concepts of "progress."

Land and Sea Ethics

Shallow approach: Landscapes, ecosystems, rivers, and other wholes of nature are cut into fragments; larger units and gestalts are disregarded. These fragments are regarded as the property and resources of individuals, organizations, or states. Conservation is argued in terms of “multiple use” and “cost-benefit analysis.” Social costs and long-term ecological costs are not included. Wildlife management conserves nature for “future generations of human beings.” The erosion of soils or of groundwater quality is noted as a human loss, but a strong belief in future technological progress makes deep changes seem unnecessary.

Deep approach: Earth does not belong to human beings. The Norwegian landscapes, rivers, fauna and flora, and the surrounding sea are not the property of Norwegians. Human beings only inhabit the land, using resources to satisfy vital needs. If their nonvital needs conflict with the vital needs of nonhuman life-forms, human beings might yield. The destruction now going on will not be cured by a technological fix. Current arrogant notions in industrial (and other) societies must be resisted.

Education and Scientific Enterprise

Shallow approach: The degradation of the environment and resource depletion necessitate the further training of experts who can advise on how to combine economic growth with the maintenance of a healthy environment. We are likely to need highly manipulative technology when global economic growth makes further degradation inevitable. The scientific enterprise must continue giving priority to the “hard” sciences. This necessitates high educational standards with intense competition in relevant “tough” areas of learning.

Deep approach: Education should concentrate on increased sensitivity to nonconsumptive goods and on such consumables as we have enough of for all, provided sane ecological policies are adopted. Education will therefore counteract the excessive valuation of things with a price tag. There should be a shift in emphasis from “hard” to “soft” sciences, especially those that stress local culture and global cooperation. The educational ob-

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

jective of the *World Conservation Strategy*, “building support for conservation,” should be accorded priority within the deeper framework of respect for the biosphere.

In the future, there will be no shallow movement, if shallow policies are increasingly adopted by governments and, thus, need no support from a special social movement.

Why a “Deep” Ecology?

The decisive difference between a shallow and a deep ecology movement hinges on the willingness to question, and to appreciate the importance of questioning, every economic and political policy in public. The questioning is “deep” and public. It asks *why* more insistently and consistently, taking nothing for granted. Deep ecology can readily admit the practical effectiveness of anthropocentric arguments. “It is essential for conservation to be seen as central to human interests and aspirations. At the same time, people—from heads of state to the members of rural communities—will most readily be brought to demand conservation if they themselves recognize the contribution of conservation to the achievement of their needs, as perceived by them, and the solution of their problems, as perceived by them” (IUCN 1980: sec. 13). Since most policies serving the biosphere also serve humanity in the long run, they may, at least initially, be accepted on the basis of narrow “anthropocentric” arguments.

Nevertheless, such a tactical approach has significant limitations. There are three dangers. First, some policies based on successful anthropocentric arguments turn out to violate or compromise unduly the objectives of deeper argumentation. Second, the strong motivation to fight for decisive change and the willingness to serve a great cause are weakened; and, third, the complicated arguments in human-centered conservation documents such as the *World Conservation Strategy* go beyond the time and ability of many people to assimilate and understand and also tend to provoke interminable technical disagreements among experts. Special-interest groups with narrow, short-term exploitative objectives that run counter to saner ecopolicies often exploit these disagreements and thereby

stall the debate and steps toward effective action. When arguing from deep ecological premises, one need not discuss at all most of the complicated proposed technological fixes. The relative merits of alternative-technology proposals in industrial societies concerned with how to increase energy production are pointless if our vital needs have already been met. The focus on vital issues activates mental energy and strengthens motivation. The shallow environmental approach, on the other hand, tends to make the human population more passive and less interested in environmental issues.

The deep ecology movement tries to clarify the fundamental presuppositions underlying our economic approach in terms of value priorities, philosophy, and religion. In the shallow movement, argument comes to a halt long before this. The deep ecology movement is therefore “the ecology movement that questions deeper.”

The terms *egalitarianism*, *homocentrism*, *anthropocentrism*, and *human chauvinism* are often used to characterize points of view on the shallow–deep ecology spectrum. These terms, though, usually function as slogans that are open to misinterpretation. They can imply that human beings are in some respects only “plain citizens” (Aldo Leopold) of the planet on a par with all other species, but they are sometimes interpreted as denying that human beings have any “extraordinary” traits, or that in situations involving vital interests, human beings have no overriding obligations toward their own kind. They have!

In any social movement, rhetoric has an essential function of keeping members fighting together under the same banner. Rhetorical formulations also serve to provoke interest among outsiders. Of the better-known slogans, one might mention “Nature knows best,” “Small is beautiful,” and “All things hang together.” Clearly, all things in the universe do not hang together at the level of quantum physics or relativity theory: the slogan only expresses a doctrine of global, not cosmic, relevance.

Only a minority of deep ecology supporters are academic philosophers such as I. Although deep ecology is not a finished philosophical system, this does not mean that movement philosophers should not try to be as clear as possible. So a discussion of deep ecology as a derivational system may be of value.

Deep Ecology Illustrated as a Derivational System

Underlying the eight tenets or principles above are still more basic positions and norms, which reside in philosophical systems and various world religions. Schematically, we may represent the total views implied in the movement by streams of derivation from the most fundamental norms and descriptive assumptions to particular decisions in actual life situations (see figure 2, chapter 9).

This pyramidal model has some features in common with hypothetico-deductive systems. The main difference, however, is that some sentences at the top (deepest) level are normative, and are preferably expressed by imperatives. This makes it possible to arrive at imperatives at the lowest derivational level, the crucial level in terms of decisions. Thus, there are *oughts* in our premises, as well as in our conclusions. We do not move from an *is* to an *ought*.

Just as in a hypothetico-deductive system in physics, where only the two upper levels of the pyramid are thought of as forming physics as a system, so also in normative systems only the upper levels are considered to be part of the total system. The sentences in the lowest part are changing from day to day as life situations change.

This derivational structure of a total view must not be taken too seriously. It is not meant in any restrictive way to characterize creative thinking within the deep ecology movement. That thinking moves freely in any direction. Nevertheless, some of us with professional backgrounds in science and analytical philosophy find it helpful.⁵

Answers to ultimate questions—that is, the highest normative principles and basic assumptions about the world—occur in the upper part of the derivational pyramid. The first three basic principles of deep ecology (as outlined above) belong to the upper level of the pyramid because they assert, in a general way, that life in its diversity is a value in itself and thus forms a norm against undue human interference. The next four (4–7) tenets belong to the middle region because they are more local; their purview is what is going on at present. They include factual claims and projections about the consequences of current policies in industrial and nonindustrial countries. An application of the last tenet (8) is at the lowest derivational level because it imposes an obligation to take part in actions to change poli-

cies. Such an obligation must be derivable from principles higher up in the pyramid.

There are a few propositions at the top of the pyramid, a great variety at the middle level, and innumerable recommendations at the bottom.

Multiple Roots of the Deep Ecology Principles

The deep ecology movement seriously questions the presuppositions of shallow argumentation. Even what counts as a rational decision is challenged, because “rational” is always defined in relation to specific aims and goals. If a decision is rational in relation to the lower-level aims and goals of our pyramid but not in relation to the highest level, then the decision should not be judged to be rational. If an environmentally oriented policy decision is not linked to intrinsic values, its rationality is yet undetermined. The deep movement connects rationality with a set of philosophical and religious foundations. One cannot expect the ultimate premises to constitute rational conclusions. There are no “deeper” premises available.

The deep ecological questioning reveals the fundamental normative orientations. Shallow argumentation stops before reaching fundamentals or jumps from the ultimate to the particular, that is, from level 1 to level 4.

It is not only normative claims that are at stake. Most (perhaps all) norms presuppose ideas about how the world functions. Typically, the vast majority of propositions needed in normative systems are descriptive. This holds of all levels.

Notice, however, that it does not follow that supporters of deep ecology must have, on ultimate issues, identical beliefs. They do have common attitudes about intrinsic values in nature, but these can, in turn (at a still deeper level), be derived from different, mutually incompatible sets of ultimate beliefs.

Thus, while a specific decision may be judged as rational from within the derivational system (if there is such) of shallow ecology, it might be judged irrational from within the derivational system of deep ecology. What is rational within the deep ecology derivational pyramid does not require unanimity in ontology and fundamental ethics. Deep ecology sup-

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

port as a conviction, with its subsequently derived practical recommendations, can follow from several more comprehensive worldviews. Deep ecology is a grassroots movement, not a worldview.

Those engaged in the deep movement have so far revealed their philosophical or religious homes mainly to be in Christianity, Buddhism, Taoism, or a personal philosophy. The top level of the derivational pyramid can therefore be made up of normative and descriptive principles that belong to forms of Christianity, Buddhism, Taoism, and various philosophical creeds.

Since the late 1970s, numerous Christians in Europe and America, some of them teachers of theology, have actively participated in the deep ecology movement. Their interpretations of the Bible and their theological positions in general have been reformed from what was, until recently, a crudely anthropocentric emphasis within Christianity.

There is an intimate relation between some forms of Buddhism and the deep ecology movement. The history of Buddhist thought and practice, especially the principles of nonviolence, noninjury, and reverence for life, sometimes makes it easier for Buddhists to understand and appreciate that movement than it is for Christians, despite a (sometimes overlooked) blessedness that Jesus recommended in peacemaking. I mention Taoism chiefly because there is some basis for calling John Muir a Taoist.⁶

Ecosophies are not religions in the classical sense, but general philosophies inspired by ecology. In the next section I will introduce Ecosophy T.

The adherents of different religions and philosophies disagree and may not even ultimately understand each other at the foundational levels of conviction and experience. Nevertheless, they can have important derived views in common, and these, though themselves derived, are nevertheless deep enough to form what I wish to call the upper level of the deep ecology derivational pyramid.

Some have worried that the mixture of religion and environmentalism could prove a source of dogmatism, intolerance, and "mysticism" (in the sense of obscurantism). So far, there is no evidence that this is happening. Nature mysticism has little to do with obscurantism.⁷

Ecosophy T

The main theoretical complaint against the shallow ecology movement is not that it is based on a well-articulated but incorrect philosophical or religious foundation. It is, rather, that there is a lack of depth—or complete absence—of guiding philosophical or religious foundations.

In his excellent book on how to “live in the environment,” G. Tyler Miller (1983: 489) writes:

The American attitude (and presumably that of most industrialized nations) toward nature can be expressed as eight basic beliefs [four of which are reproduced here].

1. Humans are the source of all value.
2. Nature exists only for our use.
3. Our primary purpose is to produce and consume. Success is based on material wealth.
4. Production and consumption must rise endlessly because we have a right to an ever increasing material level of living.

Miller adds an important reservation:

Although most of us probably would not accept all of these statements, we act individually, corporately, and governmentally as if we did—and this is what counts.

When they are so badly exposed, we might find that few people would explicitly subscribe to what Miller characterizes as “the American attitude.” Nevertheless, as Miller notes, most modern people (and not only Americans!) behave as if they believed such a creed. There is no articulated philosophical or religious view from which “the American attitude” is carefully justified.

The shallow movement has not offered examples of total views comprising the four levels in our illustration. I am tempted to say that there will be no examples. Serious attempts to find a deep justification for the way life on the planet is treated today (including the threats of using nuclear “weapons”) are doomed to failure. What I say is meant as a challenge: is there a philosopher somewhere who would like to try?

My main purpose in announcing that I feel at home in “Ecosophy T” is didactic and dialectic. I hope to get others to announce their philosophy. If they say they have none, I maintain that they have but perhaps do not know their own views, or are too modest or inhibited to proclaim what they believe. Following Socrates, I want to provoke questioning until others know where they stand on basic matters of life and death. This is done by using ecological issues, and also by using Ecosophy T as a foil. Socrates, though, pretended in debate that he knew nothing. My posture seems to be the opposite. I may seem to know everything and to derive it magically from a small set of hypotheses about the world. Both interpretations are misleading! Socrates did not consistently claim to know nothing, nor do I in my Ecosophy T pretend to have all that comprehensive a knowledge. He claimed to know, for example, about the fallibility of human beings’ claims to know.

So, here is Ecosophy T (see figure 1):

Its fundamental norm is “Self-realization!” I do not, however, use this expression in any narrow, individualistic sense. I want to give it an expanded meaning based on the distinction between Self and self as conceived in certain Eastern traditions of ātman, comprising all the life-forms, and selves (jīvas) as usually interpreted in social and personal life.⁸ I use only five words: *maximum (long-range, universal) Self-realization!* If I had to give up the term fearing its inevitable misunderstanding, I would use the term *symbiosis*. “Maximize Self-realization!” could be interpreted in the direction of colossal ego trips, but “Maximize symbiosis!” could be interpreted in the opposite direction, that of the elimination of individuality in favor of collectivity.

Viewed systematically, not individually, maximum Self-realization implies maximizing the manifestations of life. So I next derive the second term, “*Maximize (long-range, universal) diversity!*” A corollary is that the higher the levels of Self-realization attained by a person, the more any further increase depends upon the Self-realization of others. Increased self-identification is increased identification with others. “Altruism” is a natural consequence of this identification.

This leads to a hypothesis about an inescapable increase of identification with other beings when one’s own self-realization increases. We increasingly see ourselves in others, and others in ourselves. This self is ex-

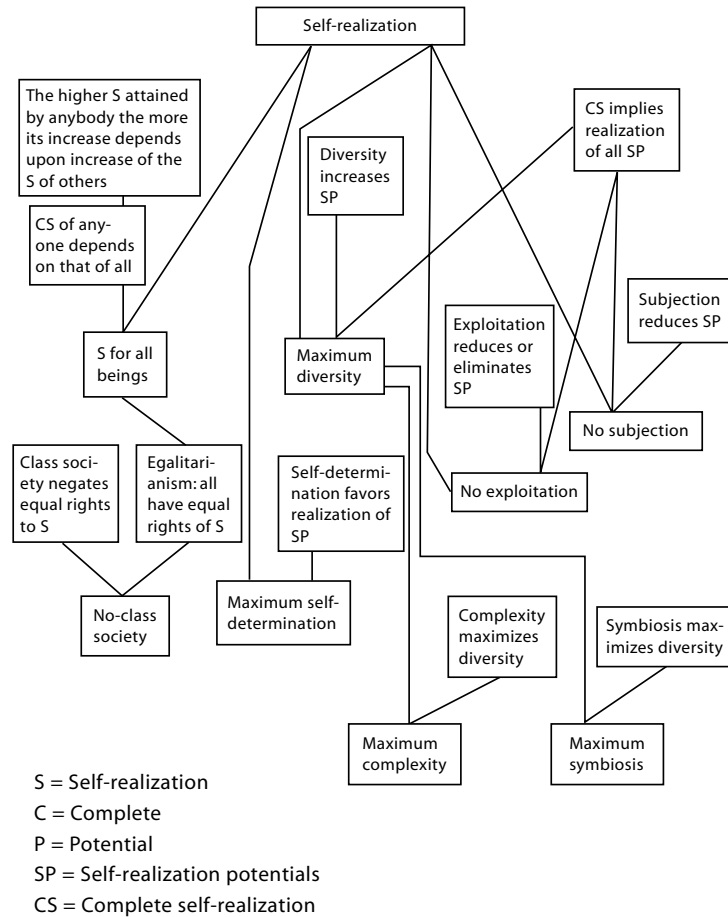

Figure 1. Ecosophy T

tended and deepened as a natural process of the realization of its potentialities in others.

Universalizing, we can derive the norm “Self-realization for every being!” From “Diversity!” and a hypothesis that maximum diversity implies a maximum of symbiosis is derived the norm “Maximum symbiosis!” Further, we work for life conditions such that there is a minimum of coercion in the life of others. And so on!⁹

A philosophy as a worldview inevitably has implications in practical situations. Therefore, Ecosophy T moves on without apology to concrete questions of lifestyle. These will obviously show great variation because of differences in *hypotheses* about the world in which each of us lives and in the “factual” statements about the concrete situations in which we make decisions. I shall limit myself to a couple of areas in which my “style” of thinking and behaving seems somewhat strange to friends and others who know a little about my philosophy. First, I exhibit a somewhat extreme appreciation of diversity: a positive appreciation of the existence of styles and behaviors that I personally detest or find nonsensical (but not clearly incompatible with symbiosis); enthusiasm for “the mere” diversity of species or varieties within a genus of plants or animals; support, as the head of a department of philosophy, of doctoral theses completely at odds with my own inclinations, with only the requirement that the authors are able to understand fairly adequately some basic features of the kind of philosophy I myself feel at home with; and a combination of *seemingly* incompatible interests and behaviors, which makes for an increase of subcultures within industrial states and might to some extent help future cultural diversity. So much about “Diversity!”

Second, I have a somewhat extreme appreciation of what Kant calls beautiful actions (good actions based on inclination), in contrast to dutiful ones. The choice of the formulation “Self-realization!” is in part motivated by the belief that maturity in human beings can be measured along a scale from selfishness to a broadening and deepening of the self, rather than measures of dutiful altruism. I see joyful sharing and caring as a natural process (which, I regret, is somewhat retarded in myself).

Third, I believe that many-sided, high-level Self-realization is more easily reached through a “spartan” lifestyle than through the material standard of average citizens of industrial states.

The simple formulations of the deep ecology platform and Ecosophy T are not meant primarily to be used among philosophers, but in dialogues with “the experts.” When I wrote to them personally, asking whether they accept the eight points of the platform, many answered positively in relation to most or all the points—even top people in ministries of oil and energy! It is, however, still an open question to what extent they

are willing to let their written answers be widely published. It is also an open question to what extent they try to influence their colleagues who use only shallow argumentation. The main conclusion is moderately encouraging: there is a philosophy of the human/nature relationship widely accepted among established experts responsible for environmental decisions, and this philosophy requires a pervasive, substantial change of current policies—in favor of our “living” planet, and not only for short-sighted human interests.

The Deep Ecology “Eight Points” Revisited

Ten years ago it was fairly common to express astonishment that people with very different philosophical and religious backgrounds could be supporters of the deep ecology movement. What did they have in common? Or, how could they have anything in common? How would they define what deep ecology really is?

The first question seemed to me the most important. It was important to emphasize that supporters of the deep ecology movement need not hold basic philosophical or religious premises in common. They should have, and use, such premises, but the premises would not all be of the same kind because of cultural differences. The deeper the differences, the better, because of the value of deep differences in cultural backgrounds.

At that time (in the early 1980s) it was important to point to views held in common. There were at least two ways in which things were clearly held in common: personal sorrow or despair was felt when environmental battles ended in defeat, and there was a corresponding feeling of joy when at least a partial victory was achieved. There was also a high degree of agreement about the need for, and acceptance of, “direct actions” of some sort, and (what to me was a great thing) a clear consciousness about the limitations of the means to be used: nonviolence. Typically, supporters had been active in the peace movement before becoming environmental activists. Reference to nonviolence should perhaps be included in the Eight Points.

This article was reprinted with permission from *Deep Ecology for the 21st Century: Readings on the Philosophy and Practice of the New Environmentalism*, edited by George Sessions (Boston: Shambhala Publications, Inc., 1995), 213–21.

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

Less clearly, the supporters had some *fairly general and abstract* views in common, or nearly in common. What the critics and doubters needed was a not too complex and detailed survey of such views, which should be put forth tentatively. The formulation of the Eight Points was the result. That these short points were called principles, or expressions of a "platform," was perhaps unfortunate. A longer name for the Eight Points is indispensable, for example: "a set of fairly general and abstract statements that seem to be accepted by nearly all supporters of the deep ecology movement."

The term *seem* is included because what is meant is not only acceptance of the Eight Points as an articulate answer to a question, but acceptance in a wider, somewhat vague sense, as in a sentence such as "Mr. A accepted Mr. B's leadership," or "In the ashram they accepted the situation that snakes and scorpions were permitted to stay in their sleeping quarters during the night." The chance might be that an ashram member, if asked, would object to allowing certain snakes to come into the room, but so far there have been no such members. It has been encouraging how people say, "Yes, of course I accept those Eight Points, but so far I have not had the words to express my attitudes." What the Eight Points have offered is mainly putting words to views that people have "always" had but have not expressed, at least not in public.

The reception of the set of eight formulations by supporters has been encouraging: from this I conclude that there is a broad similarity of views on the fairly general and abstract level. A further conclusion: the usefulness of the Eight Points as a convenient reference point suggests that alternative analogous sets should be developed. It is unnatural that only one formulation could be convenient.

The Eight Points are, of course, not intended to function as a definition of the deep ecology movement: neither as a rule-given definition of the term, nor as a plain description of how the expression "deep ecology movement" is actually used, nor as an expression of the essence of the deep ecology movement. I do not know of any satisfactory definitions at the dictionary level. For example, I do not think a dictionary entry like the following is very helpful: "deep ecology movement: a movement within environmentalism that is activist, ecocentric rather than anthropocentric, and based on nonviolent philosophical or religious views."

Looking back, I am glad to have the opportunity to make some comments about the Eight Point list, not all of which are critical:

1. It has been suggested that the Eight Points should include reference to the "all things hang together" theme. The best way of including this seems to me to be the formulation of Fritjof Capra. He suggests the following alternative formulation of point 2: "The fundamental interdependence, richness, and diversity contribute to the flourishing of human and nonhuman life on Earth."

This alternative formulation is important to me mainly because the three factors mentioned are presented as instrumental, not as values in themselves. Such a presentation does not, of course, rule out the inherent value of richness and diversity, but I have thought that inherent value must be declared explicitly in the formulation of that point. Why "must"? Conclusion: the suggestion by Capra adds to *the set of alternative formulations* of the Eight Points. (I myself have not found it possible to stick to only one way of formulating the points.)

Of course, to "hang together" as a kind of interdependence may be taken by some as a kind of threat. One hears such warnings: Remember that human beings are *unfortunately* dependent upon the health of the ecosystems. *Therefore* respect nature or you invite disaster!

In short, I have so far not found sufficient reason to include in the Eight Points a reference to the "all things hang together" theme. It should not be necessary to add that "nature mysticism" (the ultimate unity of all living beings) and similar level-1 views have no place among views that supporters may have *in common*. Views about, and feelings of, the intimacy and "hanging together" of everything may, of course, differ in terms of degree of tightness. The interdependence referred to in the alternative formulation is of the kind that supporters do, in fact, talk about.¹

I find it regrettable, however, that J. Baird Callicott, a supporter of the deep ecology movement as far as I can understand, believes that some kind of nature mysticism is *implied* in being a deep ecology supporter. Callicott (1993: 330) writes that "indeed [deep ecologists] argue that ecology teaches us that the whole of nature is the true Self." This is a strange formulation. Supporters of the movement have total views inspired in part by reactions to the ecological crisis. Such total views I have called ecosophies—I call my own Ecosophy T. Fortunately, other supporters have different ecosophies.

(One thing we have in common is that the articulation of our views is, and must be, fragmentary.) In the premise-conclusion systematization of Ecosophy T, "Self-Realization!" is designated as the one ultimate premise. Some feel at home with this, others do not. The Eight Points could not possibly contain that norm.

I do not feel bad when Professor Callicott mistakenly seems to identify my opinions with those of Mahatma Gandhi. He quotes from a section of my "Self-realization" paper (1986 [chapter 45 of this volume]), which I introduce by writing: "I do not *defend* all the views presented here: rather I primarily wish to inform you about them." Later in the section I write: "Gandhi says: 'I believe in *advaita* (non-duality). I believe in the essential unity of man and, for that matter, all that lives. Therefore I believe that if one man gains spirituality, the whole world gains with him and, if one man fails, the whole world fails to that extent.'" The quotation from Gandhi reminds me of his (and my) belief in the individual. It shook the world when, as the accused before the judge, Gandhi uttered, "The individual is the supreme concern."

Professor Callicott also writes that "scientific ecology will not support the claim that the self is in reality the Self, that the individual is identical with the world." I might join him in saying that support of that claim could mean the end of scientific ecology. At any rate, no one has, to my knowledge, found that the Eight Points imply a kind of nature mysticism, although many supporters show varying degrees of affinity with it.

Points 3 and 8 are the ones that most clearly belong to a (normative) ethic covering actions related to the ecological crisis. An *announcement* of an obligation is made in point 8, and an ethical *prohibition* is expressed in point 3. Both belong as part of an ethic of vast scope covering our relations to nonhuman beings. The search for an environmental ethic is, as I see it, a laudable undertaking from the point of view of the deep ecology movement. Some supporters would disagree, I suppose, but I am not sure that I know of any. Professor Callicott writes, "Deep ecology . . . rejects ethics outright" (1993: 325), but his four supporting quotations (three from texts by Warwick Fox and one from me) do not justify his claim. Like many others, I distinguish between an ethic as a normative system (in Professor Callicott's terminology "a conceptual system"; *ibid.*, p. 338) and acts of *moralizing*—that is, when one individual or group admonishes others to follow certain moral precepts. "We certainly need to hear

about our ethical shortcomings," I write in the article quoted by Callicott, but I have emphasized, and continue to emphasize, the rather limited motivational force of moralizing. The Kantian distinction between "beautiful acts" and "moral acts" is convenient here (see Naess 1993). Beautiful acts are compared with policies facilitating attitude changes in the direction of ecologically responsible behavior. Moreover, Warwick Fox certainly does not hold, as Callicott seems to suggest, that ethical norms having the structure of points 3 and 8 involve "narrow, atomistic, or particle-like conceptions of self."

2. In recent years considerable efforts have been made to distinguish two concepts; one is expressed by the term *intrinsic value* and the other by the term *inherent value* or *inherent worth*. What I intend to express by use of the term *intrinsic value* in the Eight Points is perhaps better conveyed by the term *inherent value*.

Some critics tell me that I must enter the professional philosophical debate about what exactly might be meant by terms like *intrinsic value*, *inherent value*, and *value in itself* (which I use in my book *Ecology, Community and Lifestyle* [1989]), but even in my comments on the Eight Points (which consist of about 400 words), entering this discussion would be misplaced. The Eight Points formulations admit of various interpretations, but they are interpretations with reasonably small differences. Although the level of vagueness and ambiguity must be within tolerable limits, professionalism would undermine the aim of the Eight Points.

3. I try in my ecosophy to be consistent in my view that individual beings, and only individual beings, can have inherent value, and not classes of individuals as such. (The term *intellectualis amor* in Spinoza's *Ethics* I likewise take to be the loving understanding of individuals.) Point 2 (which discusses diversity) makes this difficult unless landscapes, or the whole Earth, are taken to be individual beings, not classes of individual beings. If taken otherwise, I would be attributing value to some kind of mere multiplicity. I do not attach inherent value to species or families (as classes or sets of beings with more than one individual or element), but to diversity itself. From the "diversity norm," plus various hypotheses, I derive norms of priorities: the defense, for example, of threatened orders or families should have higher priority than that of species or subspecies, if there are no special reasons not to attach higher priorities to

the latter (for example, to families of insects as compared to species of mammals).

In the brief comments on the third of the Eight Points, it is not made sufficiently clear that the use of the expression "no right to" is an everyday use of *right*, as in "You have no right to eat your little sister's food!" It is not meant to be identical in meaning with "You ought not to eat. . . ." It does not imply an affirmative answer to the question of the existence of the "rights of man" or the "rights of animals." Because of vast controversies in professional philosophy about the concept of "rights," it may be unwise to use the expression "no right to" in point 3. I am not convinced about that, and the use of it opens up the good question "Why can't animals have rights?" If the answer is "Because they can have no obligations," this leads to the question "What about babies? the mentally ill?" Such discussions tend to lead people in the direction of softening their rigid views about human beings existing apart from nonhuman nature.

Concerning the term *vital needs*, several comments are readily at hand. What you *need* in your life is a small fraction of what you are led to desire in the rich countries, whereas in regions of desperate poverty the vital needs of the majority of people go unsatisfied regardless of whether or not they reduce the richness and diversity of life-forms.

4. In the 1984 formulation, population was discussed in point 5. The contents of points 4 and 5 suggest that, in terms of logical order, the population issue should be discussed in point 4 rather than point 5.

5. Many supporters of the deep ecology movement believe that a reduction in human population would, of course, be a great gain both for humanity and for nonhuman life, but they do not see how it could happen within the scope of a decent ethics. Some are willing to see reduction occur within a couple of centuries. What seems a little odd to me is that, at the same time, they can envision population stabilization (zero growth) occurring (without "nature taking over" in the sense of catastrophic wars or massive famines, or both). If transition to zero growth is thought to be practicable, why could there not also occur a population reduction of, say, one-quarter of a percent per year? Within several centuries that would make a lot of difference. A firm acceptance of the population-reduction point does not oblige one to speculate concerning how great a reduction one has in mind. That is a different question.

I seriously think that the Eight Points (or corresponding sets of points provided by other supporters) should be acceptable without hesitation to nearly all supporters of the deep ecology movement. I have found, therefore, that point 4 *might* be "softened," perhaps in the direction of formulations like the following: "It would be better for human beings to be fewer, and much better for nonhuman life-forms."

If the "decrease" or "reduction" terminology is retained in point 4, then comments should include these two points: The process of a slow but adequate reduction naturally will take more than a couple of centuries. The situation in some rich countries, where zero growth has been reached (or nearly reached), makes it important for governments to declare that nothing will be done to *counteract* a process of reduction in the next century. Those economists (and others) will be consulted who can show how a satisfactory economic situation can be maintained during the difficult transition period.

In a process of slow decrease of the population, there will be a *slight* increase in the percentage of people over the age of retirement. This could be partly alleviated by motivating a slight increase in the age of retirement. The amount of capital per person will increase slightly, as well as the availability of resources in general. The chances of significant unemployment will also be slightly reduced, and so on.

An adequate discussion of the economics of population reduction cannot be the aim of my remarks here. Both strategically and tactically, it is of central importance, in my view, that more people outside the economically richest countries realize that population reduction is compatible with maintaining, or increasing, the overall quality of life. Point 7 is meant to be relevant here. One cannot expect people in the poorer countries to believe in this point if very few people in the richest countries do.

The argument is often heard in rich countries that many sons are necessary in poor countries to provide security for one's old age. Actually, a substantial minority of people in the poor countries do not think this way (if four sons need sixteen sons, who need sixty-four, what happens then?).

Clearly, many people do not consider it possible that adults can have a close, warm relationship with small children they have not themselves produced. In many cultures, though, architecture and the use of space make it possible for small children to walk around safely and to be taken care of by

neighbors and friends. In such situations, young parents do not have to worry when they go to work, and the children might have close relationships, and even stay overnight, with “uncles” and “aunts.” Adults who wish to have small children around them, and like to spend a lot of time with them, are highly esteemed and form an indispensable part of the community. Under such conditions, one may have closer and *more durable* relations with small children than do parents in rich countries who have produced as many as four or five children.

I have used so much space talking about the population issue because I think that, in some countries, now is the time to reconsider the design of cities, and policies of spacing, so as to anticipate a slow decrease of population that may begin in the near future in some countries—say, within a couple of generations, or even sooner.

6. The deep ecology terminology was introduced, during the late 1960s, in a highly politicized environment. “Every question is a political question” was a slogan you might have heard repeated every other day in Europe during this period. The very able students of neo-Marxism and the Frankfurt School knew very well that slogans and repetitions are indispensable in a social movement. When the Green movement suddenly surfaced in European cities (in Norway with the astonishing slogan “Green Grass!”), it was laudable, in my view, that activism and the necessity of social and political change was made a central point. Economics, technology, and politics must be a subject of teaching and discussion in any “environmental” movement. The combination of points 6 and 8 is supposed to express the seriousness of this insight. That does not mean, of course, that all supporters of deep ecology must specialize in party politics or related activities.

Supporters of the deep ecology movement naturally work within the horizon of the “alternative future” movements. More specifically, they work with supporters of the Green movement (which may roughly be said to require of a society that it has largely solved the peace, social justice, and ecological sustainability problems). The intimate cooperation and mutual respect among people (whose *activism* is quite naturally focused on one, but not all, of these three problem areas) is excellent, and does not exclude strong utterances in favor of their own specialties. Such utterances strengthen our motivation.

Because the main work of supporters of the deep ecology movement concerns only a part of what is required of a Green society, there can be no such thing as a "deep ecology society." The deep ecological requirement of "wide" ecological sustainability (protecting the full richness and diversity of life on Earth), however, limits the kinds of Green societies that would be acceptable. Because (in accordance with points 1 and 2) deep ecologists view the intrinsic value, respect for, and support of deep cultural differences on a par with attitudes toward richness and diversity of nonhuman life-forms, any social or political trends of the fascist or Nazi kind run counter to the requirement of full ecological sustainability.

In Germany, some people become worried when they hear about deep ecology: "Sacredness of the soil? I remember Himmler, the terrible Himmler, talking and talking about that!" But acquaintance with the movement dispels the worries.

Critics have deplored the lack of an authoritative deep ecology blueprint for a society satisfying the requirements of the Eight Points—they are apparently looking for texts like Edward Goldsmith's *Blueprint for Survival* (1972), but updated. More or less broad visions of future green societies are expressed within the Green movement, of which the deep ecology movement is only a part. Visions are needed, but scarcely blueprints.

Personally, I envision deep cultural differences existing among green societies in different parts of the world. Valuable suggestions have been made since the 1960s, but they do not so far show, in my opinion, how diversity of thinking, acting, and cultural priorities may be normalized among future societies that satisfy the three requirements of peace, social justice, and ecological sustainability.

In any case, point 6 is not the place to go into specific requirements of social change. A vague, general suggestion along these lines is made in point 7, but I am not sure that it is a good idea to have even a point like that. It only vaguely suggests something about the general direction of the political changes needed. At any rate, it has been a great satisfaction to note that no supporters have indicated that I overrate the importance of political change as a necessary condition of surmounting the ecological crisis.

There are supporters who think that the formulation of the Eight Points has been overrated, that they do not deserve the position of importance they are sometimes accorded. If the points were taken to express *the*

THE LONG-RANGE DEEP ECOLOGY MOVEMENT

philosophy characteristic of the deep ecology movement, or even *the* principles of deep ecology, that would be, in a sense, a grave misinterpretation of those approximately 200 words used to express those points. Maybe it should be repeated more often that they *only* present an attempt to formulate what *might be* accepted by the great majority of the supporters of the movement at a fairly general and abstract level. Different sets of formulations are needed to express something similar, but in the language of supporters in the nonindustrialized parts of the world. As formulated, the Eight Points are in a sense provincial—adapted primarily to discussions among formally well educated people in rich countries.

When introducing the Eight Points in nonindustrialized societies, I use very different formulations—sometimes, for example, not speaking about the Earth at all—and I limit the intended validity of point 7 to the rich countries. It is a curious phenomenon that some people in the West think that poor people don't fight for the preservation of nonhuman beings for their own sake. In 1973 the families of a poor village in Nepal voted 46 to 0 to send their headman with a petition to *protect* their sacred mountain Tseringma (Gauri Shankar) from tourism—forgoing the vast income they might have gained. (Incidentally, the name Tseringma means “the mother of the good long life.”) Without having seen such phenomena, I would not talk about the broad *international* deep ecology movement.

In conclusion, I would like to ask forbearance for talking so much about such a small set of formulations, and only because they have so far been helpful in fostering feelings of being closely together in an immense task of supreme value.

Beautiful Action: Its Function in the Ecological Crisis

We have, most of us, a stupid reluctance to learn from philosophers who belong to “trends” or “schools” that we find lead us astray. For me, the so-called critical philosophy of Kant and Kantians belongs to such a set of trends. I say *so-called* critical. Most trend-setting philosophers have been fiercely critical of other trends, but only Kant has been fortunate enough to influence historians in the last century to such an amazing degree that in their surveys they call Kant’s philosophy critical and Spinoza’s dogmatic. This is a rather arbitrary distinction. Already in the introduction to his *Critique of Pure Reason* (1963) Kant makes assumptions with far-reaching consequences without any attempt to justify them. They may well be said to be “uncritical” and “dogmatic,” at least for some plausible and important interpretations of these terms. Both Spinoza and Kant were firm believers in fundamental ideas that they do not justify in their writings. To compare their levels of criticalness in a timeless, absolute sense presupposes that one has a third system that must be accepted uncritically. Or perhaps we don’t need that? Who knows?

In spite of Kant’s—in my opinion unfortunate—influence, in some ways his works are and will continue to be a major source of inspiration. In what follows I borrow his distinction between moral and beautiful actions. I foresee a bright future for this terminology. It offers a fairly new perspective on our actions within the realm of radical environmentalism, or more specifically within the deep ecology movement.

The distinction was introduced by Kant in a work published in 1759,

This article was reprinted with permission from *Environmental Values* (England: The White Horse Press) (Spring 1993): 67–71.

Versuch einiger Betrachtungen über den Optimismus (An attempt at some reflections on optimism), written in the period that uncritically is called his uncritical period. The distinction has been neglected by historians.

According to the terminology of 1759 an act deserves the name *moral act* if it is solely motivated by respect for the moral law: you do it simply because it is your duty; there is no other motive. Presumably a factual mistake would not spoil the beauty of an action—if you have done your duty *trying* to find out the facts of the case.

Suppose you do your duty—you perform the action that the moral law prescribes—but not *just* because of respect for the moral law. You perform the act because you are inclined to act like that, or at least partly because you have the inclination. It “feels natural” to do it. In that case Kant calls the act *beautiful*. It is a moral not an immoral act. An immoral act is one that conflicts with the moral law. The beautiful act is in Kant’s view a morally complete act because it is benevolent. Benevolent action expands our love to embrace the whole of life. It completes us and perfects us (Kant 1992: 78ff.).

It is not Kant’s habit in his main works to offer examples, but in his *Groundwork of the Metaphysics of Morals* (1949) he offers an interesting one. It is one’s duty, he says, to strive to keep alive, and there is a spontaneous inclination to do that. If you act more or less from the inclination to stay alive, the actions are not morally significant. Kant then paints a picture of a thoroughly unhappy human being who consistently desires to die but continues to try to stay alive, motivated solely by duty. This person acts in a morally right way according to Kant. Today, many people do not think it is always a duty to try to stay alive. In special cases, yes, notably because of the unhappiness or destitution of one’s own children and spouse. The temptation to follow inclination and make an end is resisted solely because one conceives it a duty to continue. Here the term *beautiful act* seems to me to be appropriate. One may in a philosophical seminar differ about the exact relation between respect for the moral law, respect for a moral duty, and respect for a duty, but the conclusions and proposals in what follows do not seem to be gravely affected by this outcome.

Presumably Kant would not deny that it may make people glad when they do their duty. The inclination may not be there, they may find it

painful or even cruel, as in a war, to do it, but they are glad *that* they resist the temptation *not* to do it. There is a conflict, a situation involving stress, we might say today. When we act beautifully no conflict of feelings is involved. It is above all characteristic of beautiful acts “that they display facility and appear to be accomplished without painful toil.” Incidentally, Kant entertained the opinion that women, more often than men, act beautifully, from compassion and goodheartedness. Men’s morality has the form of nobility, not beauty, but nobility is “extremely rare.”

So much for the Kantian distinction itself. I now turn to its application in countries manifesting an increase of ecological unsustainability and large-scale destruction of the habitats of other living beings.

The individuals and institutions trying to influence ecologically highly relevant actions in the right direction manifest roughly three different strategies: appeal to the *usefulness* of ecologically positive actions, emphasis on *moral obligations*, and inducement to develop certain attitudes—*inclinations* in Kantian terminology.

Recently there has been in Norway and other countries an upsurge of interest in environmental ethics at the governmental level. It is accepted that there is a moral aspect, that both individuals and their governments have a *duty* or *obligation* to act in ecologically responsible ways. The moral appeal is gaining ground among policy makers. Sums of a different order than before have been earmarked for ethical studies as a follow-up to the Brundtland Report (United Nations 1987). No similar sums are available, or will in the near future be available, for the study of attitudes toward nature and the conditions favorable to changes in the direction of ecologically responsible actions on every level, including the governmental. These changes may in Kantian terminology be called changes in the direction of a greater inclination to act in ecologically responsible ways. An act in the sphere of efforts to overcome the ecological crisis is a moral act if, and only if, it is motivated by the call to do our duty. Then there are acts with ecologically beneficial results that “display facility and appear to be accomplished without painful toil”—they are *beautiful* acts within the realm of ethically and ecologically relevant contexts. Again incidentally: insofar as we rely on Kant’s judgment, we should expect women to be the main driving force in fostering ecologically relevant beautiful acts.

A very common comment by people hearing a description of deep ecology for the first time is “But I’ve always thought this. I just did not have words for it.” They presumably had acted beautifully, without toil, and without words! It is unnecessary to add that the information “This means you have always acted beautifully!” might have made them proud and eager to continue.

Obviously, there is always the possibility that a beautiful act does not have the intended short- or long-range consequences that were intended. This applies in principle, according to Kant, to every action. When a policy is chosen on the basis of its usefulness or on the basis of morality, there is also this fundamental uncertainty. During the first great green wave (the late 1960s and early 1970s), millions developed the habit of turning off the electric lights when they served no immediate purpose. To leave them burning was difficult, unnatural. Then came sceptics repeating that the useful life of a lightbulb would be severely shortened if turned off and on “too much,” and to make a new bulb would consume much energy and resources. Many felt frustrated because they saw the uncertainty of both strategies: the calculation of the basis of utility versus reliance on an acquired natural inclination.

People badly informed *may* cause small ecological disasters, making false judgments of a factual character. Today more than ever it is one of our duties to keep informed; the better we are informed, the better our basis for predicting consequences.

Acting from inclination is superior to acting from duty. This vague announcement needs comment. First, acting from duty requires conscious analysis of the situation and does not exclude acting in spite of strong disinclination. The sense of duty is generally not very strong, and because conscious analysis is required, or often required, the ways of avoiding unpleasantness through talk are considerable. “It *seems* it is now my duty to do such and such, but close analysis shows that I really do not need to do such and such.”

If it is urgent to have people behave in a certain way in a particular situation, the question “Are there any ways we could make them *inclined* to act (energetically and nonviolently) in that way?” has priority. There are not many noble heroes, and if people are influenced to act from inclination, a stable habit is formed, whereas the moral act, at least as it seems to be con-

ceived by Kant, normally does not form a habit. If it forms a habit, it starts feeling natural, and an inclination occurs. In short, the moral act glides into a beautiful act. In the terminology of social science, norms are *internalized*. Perhaps Kant has underestimated this development. It increases the importance of appeals to moral capacity, but it does not reduce the importance of processes that tend to induce inclination directly, internalization with verbalized normative appeals: utterances like “See how nice this animal (flower, landscape, . . .) is” or “I wish I could help these people who are forced to live in this polluted area; such work would make me happy!” There are appeals through body language that induce joy and a process of identification. Such processes make up the nonreflective imitation and adaptation to society of children.

In his monumental *Kritik der praktischen Vernunft* (Critique of practical reason), Kant goes deeper, but I shall not bring this work into our discussion. We have such and such a special duty *in* such and such kinds of situations. Mostly the adequate reason in answer to the question “Why do we have that duty in that kind of situation?” is in terms of higher-order moral norms combined with a relevant classification of the kind of situation at hand. Duties are *relational*, a term better suited than *relative*. Intense, protracted questioning more or less inevitably leads in the direction of codified systems of normative ethics. It has been done most thoroughly by the Catholic Church in the more stable Middle Ages. Here it is only relevant to remind us of the moral *corrigibility* of any concrete announcement of a duty in a concrete situation, and the analogous need for change in the direction of a beautiful action. Hypotheses about the “facts” of the situation are involved.

What are the main ways to promote more and more consistently beautiful actions in the fight for ecological sustainability? This is a battle that has to be fought by individuals in their private capacity and by all sorts of institutions in the wide sense.

It is easiest to start with educational institutions in the materially rich countries—from kindergartens to postgraduate schools. In the kindergartens, the body language of the respected people taking care of the children is decisive. The care and respect manifested in every interaction with every living being has immediate and strong effect. One of the necessary

conditions is the presence of such beings. In Tokyo and many other places we find kindergartens (children gardens!) practically without any noticeable nonhuman life-forms except some occasional flies, which are treated as intruders. Much of the space is occupied by various mechanical contraptions.

In elementary schools, knowledge is often taken to be as important as appreciation, insight, feelings of nearness and of wonder. (Children are conceived as beings who must be useful, successful, and well entertained.) The socialization process is important, but unhappily the “environment” children are mostly adapted to today is the extremely poor communities of human beings, dogs and cats, and perhaps some spectacular, big plants, roses, and so on. The teachers are not expected to manifest love and respect for life, nor to reveal the difference between life quality and standard of living in their interactions with the children.

At the other end of the formal teaching, the postgraduate seminars, even when life-forms are studied, the style in which they are taught is from the viewpoint of an observer, not a participant. Field trips are rarely made in silence such that students can hear clearly what trees or tiny animals and plants are telling them. The focus on interaction with fellow students is permitted to go on as if they were alone and not together with a myriad of beings. Nor are they taught to express what they *really* experience and what gestalts they participate in, leaving subject-object relations out. They may obtain their doctorates without ever *sensing* what they are talking about, and if they have gained cognition (not only knowledge) of the third kind (Spinoza), they are not stimulated to consider how to *inspire* others, how to *lead* them without many words to acquire the third kind, the understanding love and loving understanding (*intellectualis amor* = *amor intellectualis*).

When we proceed to the subject of institutions, the social and political framework of the individual, practically nothing is done to protect the insights a minority has gained and to stimulate further gains. The United Nations *World Charter for Nature* (1982) is not taken seriously when it proclaims the intrinsic value of Nature independent of narrow usefulness for human beings.

What about the sphere of policies for fisheries? Is the Kantian distinction relevant? The leaders of organized labor and the politicians of the labor party—for example, in Norway—know that previous policies have been disastrous for the richness and diversity of fish in vast areas. They

know they have to propose exasperatingly small quotas. This perpetuates high unemployment. Their duty is clear, but the unemployed fishermen are furious. The political life of the leaders is in this situation precarious. The temptation to propose somewhat bigger quotas is normally there, but for the few who have internalized ecological norms, there is no temptation whatsoever. To propose unpopular regulations based on ecological considerations is the only, and the completely natural, thing to do. Of course, they are risking their political life. But with joy? Certainly not. With inner satisfaction, yes. As a moral act in the Kantian sense? Perhaps.

Richness and diversity *must* be increased. This goal is so evident that to say it to oneself in words is superfluous. A labor party minister of fisheries resigned recently after having been able to establish strict quotas. She presumably had had enough unpleasantness from the furious fishermen who had lost their jobs. Had she acted beautifully? I think the Kantian distinction works better for people who do not have the kind of power and responsibility of leaders in Western democracies.

In short, there is little understanding that fostering *inclination* is essential in every aspect of socialization and acculturation and therefore also in the global ecological crisis. Moralizing is too narrow, too patronizing, and too open to the question “Who are *you*? What is the relation of your preaching and your life?” An invitation to act beautifully, to show beautiful acts rather than talk about them, to organize society with all this in mind, may recognize and acclaim such acts, and be a decisive factor that at last will decrease the unsustainability. “Tell me about your beautiful acts today! Do the authorities encourage such acts?”

What I have offered for reflection is a small variation in our perspective, looking at what goes on in terms of a Kantian distinction. Thank you, Immanuel.

Deep Ecology and Lifestyle

It is perfectly meaningful to talk about the lifestyle characteristic of the deep ecology movement. One must only avoid thinking that it is, or should be, a definite, definable, fully coherent way of life, clearly different from all others.

The deep ecology movement includes a great number of definite, more or less easily definable *tendencies* and *attitudes* that show themselves in action. Some supporters of the movement seem to reveal many of the attitudes, and no tendencies that are in blatant opposition. One should not, however, look for “complete consistency,” whatever that might mean. It would be practically impossible to formulate criteria for a consistent deep ecological lifestyle. Every formulation would have to be vague and highly dependent on terminological idiosyncrasies.

It is agreed that it is important to clarify ecological consciousness. There is, however, always the danger that consciousness only fragmentarily colors action. In Kierkegaard’s words, a philosopher may build a castle but himself *live* in its doghouse.

I have found it most fruitful simply to list tendencies and attitudes characteristic of the deep ecology movement. I have focused on Scandinavia and have freely indulged my own terminological preferences. The order here adopted is not intended to reveal differences of importance, nor does it worry me that some items are overlapping, or that many are related as genus to species, or as family to genus.

This article was reprinted with permission from *Deep Ecology for the 21st Century: Readings on the Philosophy and Practice of the New Environmentalism*, edited by George Sessions (Boston: Shambhala Publications, Inc., 1995): 259–61. It was originally published in *The Paradox of Environmentalism*, edited by Neil Evernden (Ontario: Faculty of Environmental Studies, New York University, 1984).

VALUES, LIFESTYLE, AND SUSTAINABILITY

1. Use of simple means. Avoidance of unnecessary, complicated instruments and other sorts of means.
2. Choice of activities most directly serving values in themselves and having intrinsic value. Avoidance of activities that are merely auxiliary, having no intrinsic value or being many stages away from fundamental goals.
3. Anticonsumerism. This negative attitude follows from (1) and (2).
4. Effort to maintain and increase the sensitivity and appreciation of goods of which there is enough for all to enjoy.
5. Absence or low degree of *novophili*—the love of what is new merely because it is new.
6. Effort to dwell in situations of intrinsic value and to act rather than be busy.
7. Appreciation of ethnic and cultural differences among people, not regarding such differences as threats.
8. Concern about the situation of the Third and Fourth worlds and attempt to avoid a standard of living too much different from and higher than that of the needy (global solidarity of lifestyle).
9. Appreciation of lifestyles that are universalizable and are not blatantly impossible to sustain without injustice toward fellow human beings or other species.
10. Preference for depth and richness of experience rather than intensity.
11. Appreciation for and, when possible, choice of meaningful work rather than just making a living.
12. Effort to lead a complex, not a complicated life, trying to realize as many aspects of positive experiences as possible within each time interval.
13. Cultivation of life in community (*Gemeinschaft*) rather than in society (*Gesellschaft*).
14. Appreciation of or participation in primary production—small-scale agriculture, forestry, fishing.
15. Effort to satisfy vital needs rather than desires.

There are also tendencies more obviously reflecting the specific tenets of the deep ecology movement:

16. Attempts to live in nature rather than just visiting beautiful places. Avoidance of tourism (but occasionally making use of tourist facilities).
17. Living “light and traceless” when in vulnerable nature.
18. Tendency to appreciate all life-forms rather than merely those considered beautiful, remarkable, or narrowly useful.
19. Rejection of the use of life-forms merely as means. Consciousness of their intrinsic value and dignity even when using them as resources.
20. In conflicts between the interests of dogs and cats (and other pets) and wild species, a tendency to protect the latter.
21. Effort to protect local ecosystems, not just individual life-forms. Seeing one’s own community as a part of ecosystems.
22. Objection to excessive interference in nature as unnecessary, unreasonable, and disrespectful. Condemnation of such interference—without condemning the people responsible for the interference—as insolent, atrocious, outrageous, and criminal.
23. Commitment to acting resolutely and without cowardice in conflicts while remaining nonviolent in words and deeds.
24. Participation in or support of nonviolent direct action when other ways of action fail.
25. Kinds and degrees of vegetarianism.

There are many publicly available sources for the study of deep ecological lifestyles, such as naturalists’ and alternative lifestyle periodicals. In Norway the periodical published by *The Future in Our Hands* deals extensively with the problems of youth who seek to form new lifestyle circles of friends. Perhaps more important is the direct contact with people achieved in direct actions.

In recent years the practical possibilities of a highly developed deep ecological lifestyle have been reduced in Europe by economic policies that ruin small-scale enterprises. There is also a dominant tendency to standardize and regulate education and conditions of work. In short, the structuring of society is more detailed, leaving less room for subcultural independence. On the other hand, the reaction against this trend is strong. It would have a greater impact if those who support the deep ecology movement were more

VALUES, LIFESTYLE, AND SUSTAINABILITY

active politically. There seems to be a twenty-sixth tendency, however: to find politics boring or distasteful.

In the 1970s when the movement was new and exciting, there was a tendency to be dogmatic: One *should* use bicycles; one *should not* go by air. Bears under no circumstances ought to be shot. Hunting, even for ecological reasons, should be avoided. One should not visit nonindustrial cultures because it would tend to weaken them. One should avoid every sport requiring mechanical means. Agriculture ought to be biodynamic; no poisons should be used. The list could go on. Today there is more wisdom, fewer rigid rules, and the old Indian prayer is taken more seriously: "Great Spirit, grant that I may not criticize my neighbor until I have walked a mile in his moccasins."

Expert Views on the Inherent Value of Nature

What Is the Philosophical Position of Those Who Influence Environmental Decisions?

Are Norwegians more favorably or less favorably disposed toward the environment than the policies enacted by the Norwegian government suggest?

The debate among the political parties has presupposed for generations that the positions adopted on various issues may be located on an axis extending from left to right. The positions in the environmental debate cut across this axis. Therefore, we must picture this debate in at least two dimensions. There are good reasons for locating the positions on environmental issues within a triangle delimited by red, blue, and green sides. The green side has not, however, received much attention by the political parties. It is therefore not unreasonable to assume that Norwegians today may be more favorably disposed toward the environment than party politics suggest. We have not had sound reasons for moving beyond mere suspicion on this point until the 1980s. However, unless favorable dispositions toward the environment are expressed in entirely different ways in Norway than they are in the United States, England, and West Germany, we may today on a firm basis assume that *Norwegian policies are more hostile toward the environment than public opinion warrants*. Our highly praised democracy seems to fall short on this issue.

One investigation of public opinion in the United States, England, and

This article was originally published as "Ekspertenes syn på naturens egenverdi" (Trondheim, Norway: Tapir Forlag, 1987). It was translated from the Norwegian by Iver Ørstavik.

West Germany provides particularly strong reasons for the presumption that most people want policies more protective of the environment than those supported by certain elites—for example, union leaders, elected and appointed officials, and business executives. This poll was undertaken in 1982 and appeared in Lester W. Milbrath's *Environmentalists: Vanguard for a New Society* (1984). The questionnaire employed in the poll contained a large number of questions about relations between human beings and nature. Most of the questions addressed relatively specific and controversial issues. The responses were surprisingly consistent with positions adopted by the more radical branch of the environmental movement.

One of the most striking features of political arguments used to decide for or against intervention in free natural processes is that *respect for nature in itself* is not mentioned. What is considered almost exclusively is the narrow utility value for human beings that may result from such intervention. This has influenced environmental activists to adopt certain assumptions regarding the environmental attitudes of "power holders."

One widespread assumption is that politicians, bureaucrats, and the "experts" that have made their services available to them share views on the relationship between man and nature that are profoundly different from the views held by the environmentalists themselves. They argue that the experts both subscribe to a mechanistic philosophy of nature and support the prevalent engineering attitude, celebrating dominance, control, and manipulation. If the power holders speak of how fond they are of nature, environmentalists may easily respond by reminding them that such emotions are insufficient for grounding the proper respect: men who are very fond of women may nevertheless fail to pay full respect to the inherent value of women or the value of womanhood itself.

I have objected to such assumptions. I have maintained that politicians, bureaucrats, and experts probably do *not* share fundamental views that are less supportive of nature than the views held by environmental activists. I suggest that the causes for our society's often hostile environmental policies be sought elsewhere. Investigations that delve more deeply into the reasons for the neglect of environmental problems, reasons that may be at work even when the fundamental values of the individual power holder *would* favor more extensive environmental protection, ought to be placed high on the agenda for the remaining part of the 1980s and onward.

As a preparation for such investigations, I have suggested that we attempt to find out what philosophies of nature are actually subscribed to by those working as advisers to government and business authorities, people who are also perceived by the common person as “experts” on environmental issues.

This article discusses a preparatory investigation of this kind, which I carried out in the spring of 1985.

The Questions

In January 1985, I mailed a personal letter to 110 Norwegians who in their work deal more or less directly with environmental questions. The sample was not intended to secure a reliable representation of predominant attitudes in the professions they represent, either for Norway as a whole or even for parts of the country. The sample is too narrow to justify such conclusions. A more extensive investigation therefore ought to be carried out in the future. Nevertheless, the professional positions occupied by these people are important enough to make a presentation of their views interesting.

The letter consisted of: (1) an introduction; (2) eight questions, or rather points, to be discussed concerning the inherent value of nature and related topics; and (3) an explanation of and commentary on these questions.

The text of the letter follows:

Dear [name inserted]:

Among the activists in the movement for environmental protection, certain assumptions seem to prevail about the attitudes of “experts,” i.e., persons presumed to possess advanced knowledge of practical relevance about a restricted topic, on environmental protection. These assumptions are that the “experts” are not eager to protect nature for its own sake and that they are only concerned about protection that is useful for humankind, particularly in the short run or within the bounds of what is politically possible today.

These assumptions may reflect the fact that the expert opinions referred to in the mass media are usually answers to questions that are narrowly focused on issues of the day—therefore they do not represent the personal priorities or fundamental attitudes of the “expert.” Such priorities and attitudes are seldom stated,

VALUES, LIFESTYLE, AND SUSTAINABILITY

except in private circles. Some may also feel that airing opinions in the mass media on issues to which they cannot speak with professional authority will damage their professional status or their reputation for sober judgment.

Thinking that such assumptions are not justified, and that a more correct judgment of these matters will serve environmental interests, I have decided to inquire informally about the opinions of a number of experts on the relationship between human beings and nature. The inquiry will not be posed in general terms. It will relate to eight theses that are presented below, each with a commentary attached to it. I hereby invite you to participate in this inquiry.

I will certainly appreciate answers extending beyond a simple rejection or rejoinder to the views expressed, as you choose to interpret them. And I will be grateful for whatever opinions you might want to add.

Your response to this inquiry will in no circumstances be publicized without your express consent.

Yours sincerely,

Arne Naess

On the inherent value of nature and related topics:

1. The flourishing of human and other forms of life on earth has value in itself. The value of nonhuman forms of life is independent of their utility in the service of narrow human ends.
2. The diversity and richness of forms of life has value in itself, and contributes to the flourishing of life on Earth.
3. Human beings have no right to reduce this diversity and richness, except in order to satisfy vital needs. (See the comments on the term *vital*.)
4. A full development of the potentiality of individual human beings and cultures is compatible with a reduction of the human population. The protection and development of the diversity and richness of other forms of life presuppose such a reduction.
5. At the present time, the magnitude and character of human intervention in natural processes is indefensible, and the worsening of the situation is accelerating.
6. Essential improvement presupposes changes in fundamental economic, technological, and ideological structures. Such changes will have to make possible the joyful experience “that all things cohere” and dissolve the motives that support belief in the so-called “conquest of nature.”

7. Changes in our way of life will involve a search for a better quality of life rather than simply a rising standard of living. There will be a turn from a narrow focus on means to a concern for fundamental purposes.
8. Those who accept these theses are responsible for contributing directly and indirectly to realizing such changes.

Comments:

Point 1. *Inherent value* is employed synonymously with the term *value in itself*. Something possessing inherent value will not have to serve as a valuable means for some other purpose. Inherent value is independent from any such purposes. This, however, does not preclude that which is inherently valuable from also possessing value as means. A hike in the forest, or good company among friends, may possess both kinds of value.

The word *narrow* in the expression “narrow human concerns” plays an essential role. A widely and deeply reflective human being will be able to adopt the goal of protecting other forms of life for their own sake. Such a human being will see the inherent value of other forms of life and support employing means useful for their flourishing, just as he or she will support employing means useful for narrow human concerns. A society joined to such wide and deep purposes will act similarly.

Point 2. The expression “diversity and richness of forms of life” is commonly understood as referring merely to the number of species. We do, however, need to maintain parts of the wider employment of the terms *life* and *living*. The slogan “Let the river live!” formulated in the campaign to stop the damming of the Alta River in northern Norway in the early 1980s, was in this respect aimed right on target. Concern was not limited to the riverbed and the flow of water but included the complete habitat of flora, fauna, and human activities insofar as they did not disturb the life of the whole. Here I am speaking of our living planet and other large wholes (gestalts in the philosophical sense of the word), which cannot be limited to organisms in a zoological or botanical sense of the word. These applications of the terms *life* and *living* do not presuppose any particular mythology or philosophy, e.g., panpsychism. They make good sense of how we actually experience the nature within which we live.

The expression “richness” is linked to “diversity” to counter the tendency to reject only the total extinction of forms of life. It is not sufficient that somewhere on the planet there are eagles or whales of a certain species, e.g., killer whales. We must seek to maintain their communities and the places where they traditionally gather.

Point 3. If one objects that the formulation of point 3 is imperfect because it is vague and ambiguous, I argue that this rests on a misunderstanding of what may be achieved in a text consisting of so few words when the purpose is to articulate principles of some depth.

If I am to approach the practical problems more closely, a commentary on the expression “vital needs” will be required. The employment of the expression in point 3 bears a family resemblance to the employment of the term *fundamental needs* in social psychology. (I use the weak expression “family resemblance” because “vital,” as employed in point 3, is more philosophically than scientifically colored.) My use of the expression here is clearly oriented against a strikingly common interpretation of point 3: that anything considered necessary by a person or a group in a compromised social position may be considered a “vital need”—e.g., access to parking space, a job, the liberty to smoke cigarettes for those who feel a need for it. Such needs are not considered vital in point 3 for reasons that may be indicated by distinguishing between means and ends. It may well be that someone, finding himself in a compromised situation in which he can keep his job only if given access to a parking space, could have his fundamental needs left unsatisfied if he loses his job. A parking space in this case could be viewed as a more or less necessary means for satisfying some vital need. There are, however, too many ways in which the employment of this means can be made obsolete, thus countering any need to count access to a parking space as a vital need. These comments are, of course, not sufficient for preparing clarifying decisions, but they may at least help indicate the direction they ought to take.

The expression “diversity” is naturally interpreted as indicating the diversity of species, and this is an important part of the subject matter that it is intended to cover. However, the very broad sense of the expression “forms of life” implies that a diversity of landscapes and, more generally, landforms is also included in its scope. Environmental protection today includes such activities as the preservation of traces of old habitation and the human activities associated with them in former times. This includes the protection of old landforms, such as the peculiar geological formations of the Quaternary period.

Point 4. The formulation of point 4 may be a bit too categorical. However, if the emphasis is put on preserving richness as interpreted in the commentary to point 2, the last claim in point 4 is difficult to reject. One might, alternatively, recognize the unique expansion of the human species around the globe but nevertheless refrain from claiming that a subjugation of such magnitude is correct. Conced-

ing to such a claim would imply an awareness of the power of subjugation as such.

Point 4 is claimed to be valid only insofar as no changes of fundamental economic, technological, and ideological structures are under way, i.e., insofar as point 6 is not satisfied. If such changes are under way, the population problem may be reconsidered. It would, however, be irresponsible to presuppose that such deep changes will occur in the near future.

In criticizing point 4 it is necessary for one to consider the theoretical character of the thesis. Nothing is stated regarding the practical realizability of reducing the human population. Insofar as reduction is mentioned, this is motivated by the basic conviction that such reduction, if possible, would be valuable. Furthermore, it is important that the wide temporal perspective implied in this declaration of principles as a whole be given particular weight with respect to point 4. A time frame of a century will be much too short for turning the present growth in human population into a reduction. A socially and politically realistic aim would be first to stabilize population in countries with high growth rates, and second, to facilitate a very modest reduction in countries that now have nearly stable populations. Few areas of the world would, however, be exempted from restricting their population if point 4 is accepted.

Point 6. A considerable degree of consensus has been reached concerning the direction for the necessary economic, technological, and ideological changes. Point 6 could therefore be specified more concretely, if only to a modest degree—for example, by adding a list of key phrases indicating the direction for such changes, such as development of appropriate technology, an economy aimed at subsistence, decentralization of political authority, anticonsumerist agitation, public focus on life quality, enhancement of the life of local communities, and encouragement of holistic thinking.

The second sentence in point 6 counters the tendency within the shallow ecology movement to speak about our dependence on nature, the necessity to abide by the laws of nature, and the threat of a backlash (should we fail to abide by these laws) as if nature were an unfortunate hindrance to the flourishing of human life. The deep ecology movement does not share this discouraging view on the relationship between human beings and nature. In contrast, it builds on the experience of the invigorating intensity of this relationship.

Point 7. This point, perhaps more than any of the other points, is one that other participants in the environmental movement would have expressed in different terms.

The Responses

This rather long letter was sent to 110 “experts,” many of whom could perhaps be better described as high-ranking public officials. Thirty-three responses were received, some of them consisting of many typewritten pages, others more in line with a simple statement of agreement or disagreement with each question or point.

What impression did the responses make on me as a professional academic philosopher? I was very favorably impressed by the *quality of the answers*. Some of them ought to be published in extenso; this, unfortunately, is not the appropriate place.

I am grateful that so many respondents were willing to go along with the peculiar terminology used to characterize the eight points in the letter. It is also clear that their formulations occasionally abound with a kind of friendliness toward nature that would have reminded the directors of the Norwegian Water Resources and Energy Administration of the polemics of the Mardøla and Alta conflicts.¹ The answers, however, are frank, direct, and often agreeably unpretentious. A list of the respondents, all of whom have kindly given permission to be cited by name, is provided as an appendix to this article (see p. 183).

Excerpts from the Answers

In the following I quote some characteristic opinions on the eight points presented in my letter. I have taken the liberty to introduce and comment on the responses.

Responses to Points 1 and 2

It is highly relevant, particularly from the point of view of philosophical analysis, to ask (1) what inherent value is and (2) how the assertion that something possesses such value may be substantiated. To my delight, I found that most of the respondents accepted my employment of this terminology without reservation and responded affirmatively to my claims concerning such values. Others sought to express the assertion more precisely but did not dismiss the problems raised by its employment.

What if one is unable to substantiate an affirmative response to these points? I believe some of us would then point to an Aristotelian thesis which argues that the requirement that one must be able to ground all assumptions is a sign of deficient education (*paideia*). Some premises, both normative and descriptive, must stand unsupported. The alternative is to move in circles. On to the quotations!

It is probably of great or decisive inherent value—although I am at pains arguing why, and find it particularly hard to see how this inherent value could gain general acclaim, insofar as human beings to a diminishing extent live directly in touch with, and experience, “other forms of life.” The sum total of our impressions incorporates a steadily growing part that does not originate in impulses from “other forms of life,” but instead by man-made and technologically induced impulses.

(Per Sundby)

This is a very important point, although I find the word *probably* a bit misleading insofar as it is difficult to see how the probability of statements on inherent value may be determined.

Then it is burdensome to be exposed as a reactionary. I am not, in fact, eager “to protect nature for its own sake,” but only in accordance with ideas of what is useful for human beings.

(Per Sundby)

Some would say what is useful for man is what satisfies his needs. If we divide needs into material and spiritual ones, a versatile and mature human being would recognize a need to protect nature for its own sake. Therefore, nature is useful for man.

Value is a nice word. And I have nothing to say against the term *inherent value*. But I do not understand what it means. You explain what it does not mean, and claim that it may stand for itself. This leaves me just as wise, or rather: just as stupid as before.

(Hans Chr. Ødegaard)

This answer will receive support from professional philosophers who find the expressions “inherent value” and “value in itself” problematic. I myself trust the intensively meaningful and spontaneous experience of the

value of life in a free nature. It has been encouraging to see how the pictures of Earth taken from space have supported the opinion that the Earth and its life has a value in itself, in the sense of a value independent from us, the human beings. Philosophical analysis of concepts will hardly be able to uncover some illusion on this point; the debate will likely continue.

To me, talk of value makes no sense except in relation to something or someone. Living human beings are the closest at hand, then our closest forebears, etc., down the line of animals backward in time. Further down than moths and mosquitoes, grass and debris, this becomes difficult, but nevertheless: value must be *for* something.

(Hans Chr. Ødegaard)

It is a sad thought, but let us consider it nevertheless: a catastrophe leaves only one living being on earth, a baby six months old. The absence of “something” *for* whom or which this baby has value does not deprive it of value, as I employ the expression. Some will object by arguing that the value of the baby is something that we human beings ascribe to babies in general, disregarding these circumstances. My answer will then be: Very well, but this does not stop the baby from possessing inherent value, as I see it.

I believe that we will produce results easier and faster, or more modestly: that we may move societies and nations in the desired direction more easily, by considering value *for* human beings rather than through considerations of value *independent* of human beings.

(Hans Chr. Ødegaard)

This is an important remark, and one with which I concur completely.

A key, internationally recognized publication on our topic, *World Conservation Strategy* (IUCN 1980), makes its arguments on entirely “anthropocentric” grounds: nature has to be protected because it is necessary for the health and well-being of human beings. This publication provides *politically* weighty arguments throughout. A new edition of the book might benefit from distributing the percentage of the arguments—may I suggest 97 percent centering on *narrow* human purposes and 3 percent focusing on inherent value?

The word *narrow* in point 1 is important. Achieving all-around matu-

rity, a human being would in my opinion identify so strongly with other living beings that the sight of their mistreatment would cause pain, partly independent of whether the other being feels pain. The all-around mature human being would rejoice in the wholesome treatment of other beings. Thus, the value of these other beings would be independent of their “utility” in the normal narrow employment of that term. This is part of what underlies the addition of *narrow* to point 1.

[A]ll forms of life have value for humanity. The problem is that only small parts of humanity see, and are able to see it. Also, life that at first sight appears useless, or straightforwardly harmful, is part of the ocean of components that, gathered together, provides the experience of value/beauty/greatness and the feeling of awe/affection/wonder. This experience is accessible to different and always varying parts of nations or individuals, but always only to parts. The variations are also there in the individual: it's mostly gray, although there are glimpses of the sky.

(Hans Chr. Ødegaard)

The point of view indicated in this passage is very close to the more extreme one that I defend. It implies a step-by-step elimination of the stubborn “Cartesian” reference to the human subject. One might have objections to this elimination on philosophical grounds, or for (narrow?) commonsense reasons. Many seem to be receptive to the possibility but close themselves off at a certain point:

On point 2 I agree, but I am not quite able to see that it is possible to place value except in relation to man, and therefore doubt the correctness of saying “in itself.”

I will [also] emphasize some reservations with respect to the concepts employed, as I believe evaluations of diversity and richness are human values. What you really say is that the diversity and richness of forms of life, *as it is perceived by the human mind*, has a value in itself because it responds to deep human needs.

(Per Ofstedal)

On this I will remark that employment of the expression “in itself,” as in point 2, in ordinary, nonphilosophical, but still very instructive speech, *does not exclude* a relation to human beings. Ødegaard and Ofstedal are obviously philosophically infected experts!

Now let us consider a more down-to-earth passage:

The greatest intervention in nature throughout the history of man is probably *agriculture*. It has developed tremendously through the times we have knowledge of, and man has to a very large extent conceived agriculture as a *natural part of nature*.

It is, I hope, not too indiscreet to state that this, for many of us somewhat unpleasant, truth about agriculture is not presented by an expert in the Ministry of Agriculture but by one in the Ministry of Oil and Energy. What is done to Mother Earth by us in Oil and Energy is very innocent compared to the gigantic devastation of nature caused by the latest doubling of the population made possible by agriculture. And remember: only a small part of the cultivated area is *directly* employed to produce food for human beings. It is of no use if you claim that this devastation altogether, or at least 50 percent of it, covers the vital human need of nutrition. So stop mailing complaints to this ministry alone!

(Jon Tveit)

The importance of point 2 as an independent point in relation to point 1 seems accepted by most of the respondents.

[It is] out of *this diversity* that I gather the *inspiration and joy* which, among other things, enables me to do my work as an expert in my limited field as well as possible.

(Jon Tveit)

The continuation of this passage transports us directly to the most concrete conflicts of our day:

By the words *as well as possible* I include the importance of meeting the demands for energy—which is my professional field—in ways that take external values into consideration. What would this country, for example, be like if we did not exploit waterpower as it is done today?

(Jon Tveit)

The treatment of point 7, on quality of life, will provide an opportunity to comment on this quotation. Here I limit myself to underlining Jon Tveit's commendable employment of the term *demand* instead of *need*. I also rejoice in the fact that others in the same ministry stick to the same sober language. The same cannot be said of our representatives in Parliament!

Classical social economics was oriented toward the investigation of

how human *needs* could be satisfied as far as possible, given a specific social framework. Leading social economists before the First World War employed market demands as a useful quantitative indicator of certain kinds of market behavior, but they were not used in earnest as a measure of needs. An institution aimed at securing the coverage of energy needs would, from the philosophical point of view I have adopted, have to be crucially different from one aimed at securing the coverage of energy demands without concern for the value of satisfying this demand. In Norway, energy demand has very little to do with the vital and spiritual needs of particular individuals. (The “need” for crawfish is rising, it has been declared, and may create a new and important industry.)

Responses to Point 3

Support for points 2 and 3 does not imply that one must be committed to maintaining the population of all wild animals everywhere. Per Harald Grue seems to have interpreted point 2 in this direction and expresses the following objection:

I cannot, for example, see any need or any value whatsoever in maintaining the population of wolverines in the Agder Counties, as this will entail grave conflicts with the interests we have in keeping sheep grazing in the area. I am therefore of the opinion that we may keep carnivores in selected areas of the country only, and must be ready to accept that they will be close to extinction in other parts.

Point 3 is for me the expression of a deeply felt conviction. The two key words *right* and *vital* are, of course, so vague and ambiguous that the point cannot provide anything other than a very general guide for the regulation of our behavior.

I was pleasantly surprised to see that most respondents accepted this point. The rest did not protest but merely commented on it in various ways.

. . . I would perhaps give the notion of “vital” needs a richer content than what seems presupposed by the questioner.

(Knut Dæhlin)

The important point is that my comments on the word *vital* in the letter invited a quite narrow judgment of what should count as vital, i.e.,

what is necessary for the full satisfaction of basic needs (food, clothing, shelter, and so on).

It is striking how some people, when placed before undisturbed nature, respond to it with questions such as “What can be *done* here?” or “What can be *used* here?” rather than by appreciating nature as it unfolds. Eystein Paasche describes these two different attitudes:

Before I answer your question concerning the eight formulations, I would like to remark that I am probably quite atypical among the working marine biologists of Norway in 1985. I have a romantic attitude toward nature and its diversity, and I am skeptically inclined toward technology (even if I depend on it in my research work). The scene of professional marine biologists in this country is probably dominated by people who, quite to the contrary, believe positively that all problems have a technological solution. This engineering spirit will likely permeate many of the statements produced in professional circles concerning our fjords, oceans, lakes, and rivers in the years to come. If you would like to know what the “experts” really mean, you should instead interview the engineers (I employ the word for people who have adopted a certain attitude, rather than for those who have completed a specific education).

The difference Paasche points to does not appear clearly in the responses, although it might have done if we had posed a more particular question about *what* plans for intervention in the natural environment ought to be effectuated.

Some still share the enthusiasm so well known in Ibsen’s characters. Let me quote from the play *John Gabriel Borkman* (1959: 107, 117): “[T]he waterfalls! And the quarries! And the trade routes. . . . All the wealth that lay hidden in the soil, and the rocks, and the forests, and the sea—I wanted to gather it all into my hands, to make myself master of it all, and so to promote the well-being of many, many thousands.” There is probably not much left of the egocentricity of John Gabriel among our experts, but there is, most likely, some of the implicit sense of sovereign right and joy in exercising the power to “subdue” nature.

Eystein Paasche claims to have a “romantic attitude” toward nature. What is really meant, I think, is a realistic and ecological attitude. What he calls an engineering attitude also expresses a romantic idea: of the ever more sovereign mastery of nature by man. In the nineteenth century, a real-

istic and ecological attitude was present in the art of painting, which also in its day was stamped as romantic.

Whether man has a right to do this [reduce the diversity and richness of nature] seems to be the wrong question. Man assumes such right in virtue of his power. A good, and deterring, example may be Africa today. Because of overpopulation and drought, the deserts expand. People starve and die. Do the people of Africa not also have a right to strive for survival? They do clearly attempt to cover vital needs, and may by this attempt disturb the diversity and richness of nature beyond repair. In our industrialized part of the world, we use or consume ever more of nature even if our vital needs have been satisfied for a long time.

(Jon Tveit)

Strong words! I suppose that Jon Tveit accepts the distinction between having and assuming a right. What I am alluding to here is finding out if there might also be, among experts, people who spontaneously employ expressions such as “We do not have the right” with respect to destroying the conditions that support life on the planet: thoughtless breeding of children in Norway makes it difficult to work against thoughtless breeding of children in Africa.

The blind forces of nature herself limit the populations of different species. Are these forces not sufficiently strong to set boundaries for human beings? Is there a need to propagate limits, and is there any use in moralizing? “No” is a common answer to such questions. What follows is an example of something reminiscent of this attitude:

Do human beings have less of a right than dinosaurs or deserts? Is humanity part of the life on Earth, or do we consider ourselves qualified to rise above it? . . . The dispersion and development of the human species will find its natural limits, and nature will secure this by herself.

(Bo Wingård)

Is it even questionable to employ the word *right* as done in point 3?

I am in awe before the word *right* . . . “ought not” is better than “has no right to . . .”

[Speaker not identified by Naess]

The expression “we have no right to . . .” has a sharp ethical intention,

which I am anxious to maintain. “We ought not . . .” is too submissive for the purpose.

In the context in which the expression is employed in point 3, the ethical point may be elaborated in terms of *natural law*. I believe something essential will be missing in our approach to nature if there is no intuitive response to the ethical aspect of natural law, even though such a response is not necessarily entailed in acceptance of point 3. It will be sufficient to endorse the employment of the expression “we have no right to . . .” in ordinary language, as in the sense of “You are a big boy and have no right to strike your little brother (although he may have the right to slap you one)!” By using this language, I move in a different direction than Per Schreiner, who comments:

I am unable to see the word *right* as making any sense in this context—we *have* the power, or the capacity. My arguments would not rest on the word *right* but would rather consider what is prudent and good. To me, the question is one of estimating and comparing values.

Philosophical and scientific analysis of the expression “right to,” as it is employed with reference to the diversity of nature, has not definitely *confirmed* its invalidity, its senselessness, or the impossibility of applying it with precision. Per Schreiner nevertheless formulates a well-reasoned opinion, which provides support for a different formulation of point 3.

I do not quite agree with the point as it is stated. The first part of the statement is a “credo,” which I may accept as a basic guideline. The other part—on the vital interests—seems to express an ad hoc approach that does not deserve to be subsumed under the concept of “having a right.” Another matter is that realistic and rational intervention in natural processes is required for the management of situations that are not the product of human activity. It would, for example, be wrong not to fight AIDS for the reason that diversity must be protected, both because of the overriding concern of protecting human lives and because AIDS—given that the development of the last six to eight years continues unchecked—may produce a more severe catastrophe than atomic war, and make the problem presented in point 4 superfluous.

(Per Oftedal)

Particular decisions according to the guideline *suggested* in point 3 will require our sense of judgment to handle complex circumstances. The difficulties of practically employing our sense of judgment, however, do not re-

duce the importance of principles—they merely clarify their limitations. The control of AIDS is of vital importance for humankind. When entire species of living beings are considered, virus particles are not counted.

The edifying example of AIDS provides a natural occasion for commenting on the differences among diversity of species, diversity of populations (in geographically different places), and diversity (number) of individuals. Furthermore, it highlights the distinction between extinction and a reduction in population that comes close to extinction but is capable of being supplemented by other populations (e.g., in laboratories) large enough to secure survival.

I find it difficult to take a definite stand on several singular questions, e.g., diversity, richness of nature, fishing and hunting, and the regulation of sealing. The resources may be scarce, but I understand the bitterness of Finnmark fishermen when the resources are inaccessible because political decisions bar sealing and whaling of smaller species.

(Kaare R. Norum)

A useful remark! One could also mention the complex conflict of concerns with respect to the question of preserving a Norwegian population of wolves. The long-term aim would be a Barents Sea abounding with life as it was 200 years ago—and no *bitter* fishermen!

Per Harald Grue also discusses essential matters, but they cannot be paraphrased in a few words. Here are some of his conclusions with respect to natural values such as forest zones, rough grazing areas, and other features of the cultivated landscape:

I believe it is important to underline the necessity of considering natural values, their use and exploitation, together. This seems to me to be a systematically underestimated point in the debate on environmental protection. I also believe that it is dangerous to look at these questions with a conservative outlook, which at the outset assumes that there is only one form of economic activity that may secure and preserve these values.

Responses to Point 4

No one expressed any direct disagreement on point 4. Remarkable! Nevertheless, I have succumbed to the temptation to attach the following comments:

VALUES, LIFESTYLE, AND SUSTAINABILITY

I do agree, but on the condition that the reduction is carried out in an acceptable manner. There is a huge difference between enlightenment and free consent, indoctrination and forced intervention, and terror and violence, which makes obvious that some procedures may conflict with the purpose of the reduction, and that the costs implied by the method employed may outweigh the possible benefits.

The aim must be to reduce the number of people below today's level in the long run. I believe this is an aim that will eventually be reached. The question is if it will be reached in time.

(Per Oftedal)

I have claimed for a long time that Norway at least ought to facilitate a "freeze," as reduction probably will be much more difficult and probably require more time.

Traveling in Norway, I have seen how human cultivation year after year has destroyed different areas of the natural environment and diminished natural diversity. The growth in the population that has been going on since the 1950s ought not to continue, unless the structure of habitation and our way of life are changed. On a global scale, of course, these problems achieve quite different proportions.

(Jan Økland)

Bo Wingård, in keeping with his response to point 3, raised issues regarding taking action on the problems implied by point 4:

It is not certain that we have to be eager to reduce the size of the human population. It is reasonable to assume that such a reduction will come, without anyone specially chosen pressing the matter before the time is ripe for people to make the necessary decisions themselves. The reason for this is that the requirement that there be an equilibrium between the number of living beings and the resources necessary for their subsistence is inherent in nature, and therefore also in the human species itself. See how the growth of the population apparently is under control in China, because it has been discovered that the country cannot feed more than it is able to feed today. (It is strange, really, to watch Norwegian politicians worry over a slight decrease in the growth of the Norwegian population. They are of the opinion that other countries ought to watch out for overpopulation [China, India, African countries] but do not see the advantages of a decrease in the number of people in Norway. Considering the resource base of this country, the number of people living here is certainly not too small. For a large part, we

live off the production capacity of other countries.) So far, human beings (and nature) have always found a way out of the messy circumstances and the dependence on particular resources they have created for themselves. Therefore, we have no reason to be particularly pessimistic and believe that we will not find one in the future.

Only some aspects of the changes in the circumstances of life induced by human beings *can* be reversed. This holds for the extinction of species of living beings, which might add up to a million within the next thirty years. Many other aspects may be restored only by great effort, such as the ruination of approximately 5 million acres of agricultural land every year by salinization or exhaustion, about the same area that is lost because of the spread of deserts. Other areas may be saved only by establishing new guidelines for development. The annual, overall loss to development is calculated to be approximately 20 million acres, four times as much as is lost by the spreading of deserts. If the billions of poor people in developing nations choose to employ large areas for development as we have in Norway, there will be little land left for agriculture. It is one thing to come out of a “mess” alive; it is quite another to secure an acceptable quality of life.

If we assume that one Norwegian consumes forty times as many natural resources as one person in the developing countries, the cost of 4 million Norwegians will be as large as that of 160 million in the poorest parts of the world. Thus, a reduction of Norway’s population is also required, as long as politics and lifestyle are not changed drastically.

Kåre Kristiansen was the one respondent who came close to offering a negative response to point 4:

Because the consequence of what is expressed in point 2 might lead precisely to the circumstances described in the first sentence of point 4, I was reserved with regard to point 2. I, therefore, also find it difficult to answer point 4 with a “yes.”

From Kåre Kristiansen’s statements, I infer that it was difficult not only for him to answer point 4 with a yes, but also to answer it with a no. This is of interest because the Bible can be interpreted, although on an arbitrary basis, as if it is God’s will for us to procreate as much as possible, no matter how inconsiderately we may then handle his creation.² An opposing

interpretation is developed in Norway by the movement Gathering for the Creation. The ecologically wholesome publications of this movement contain instructive quotations from the Bible.³

None of the respondents associated a reduction of the human population with misanthropy. It is also noteworthy that none found it necessary to introduce the question of whether a reduction in some aspects of quality of life might result from human population reduction. Might family life be reconstructed in a way that yielded greater gratification than before by increasing interaction with the children of others? Is a more open relationship in neighborhoods and local communities possible? Surprisingly little has been published on these central questions.

Responses to Point 5

Reasonably enough, there were no direct objections to Point 5. Nevertheless, some concerns were raised:

I do not agree with the employment of the word *indefensible*, but maybe with the alternative word *irresponsible*. All actions can probably be defended with reference to some motive or other. The point is rather that the implicit philosophy or morality is lacking or is too egoistic or shortsighted.

(Per Oftedal)

I do agree completely that we do much that is both indefensible and inconsiderate, but I am much more optimistic with respect to the possibilities of rectifying the situation without lowering our material standard of living. In many ways, a revolution has been going on throughout the 1970s with respect to pollution. The efforts made have not been widespread throughout the economy, yet some of the initiatives have proved economically advantageous for society as a whole.

(Per Schreiner)

Here, finally, we have a passage that clearly represents what many call the shallow ecological movement. It may be characterized by attitudes and assumptions such as these:

- We may be optimistic with respect to the problem of pollution, which probably will decrease and become easier to eliminate in the future.

- The material standard of living in the richest part of the world may be employed as a general standard for all people.
- The economy of our society will not have to be changed dramatically. It will prove to be economically advantageous, in the normal sense in which these words are used in our society, to eliminate ecologically unsound policies.

When people hear of the contemporary destruction of nature, they easily get the impression that the harm done per capita in our time is larger than in other times. It is important to correct this impression:

Is this the case in our time only? Think then, for example, of the crude logging in the Røros⁴ area to provide firewood for the furnace ovens, and the slaughtering of the buffalo in the United States.

(Erik Kåsa)

It is quite clear that human beings in many nonindustrial societies have behaved as thoughtlessly and irresponsibly as we do, and perhaps even worse. We are nevertheless unique by virtue of our numbers and our *capacity* for grand-scale devastation.

To Kåre Kristiansen, point 5 seemed somewhat optimistic—or perhaps naive? This goes for others as well, even if they remained silent. The sense of crisis is not apparent in all responses. Some respondents did not consider the expansion of man across the planet to have reached an extent that makes each new asphalt road and construction project a *principal* problem.

If marshland is expropriated to launch a construction project, the forms of life that belong there must find another habitat or perish. One may assume, however, that the construction project will provide room and possibilities for the flourishing of other forms of life.

(Trygve Bergland)

It is obvious that activities offering favorable conditions for some forms of life will always simultaneously deny similarly favorable conditions for other forms. What I have attempted to bring into focus in my ecological reflections, however, is how all human activities combined *together* affect the conditions for life on Earth. Trygve Bergland seems quite relaxed about the situation. Is this calmness to be envied?

Responses to Point 6

I must admit my surprise at finding only two negative, or at least clearly hesitant, responses to this thesis:

[T]his formulation may seem defeatist. I believe, first, that great improvement in the protection of the natural environment can be achieved at a small material expense, and that the material structure of life therefore does not have to be changed all that much.

(Per Schreiner)

Per Schreiner, in this passage, provides valuable insight into the shallow ecology movement: We shall be able to solve ecological problems without people living in the industrialized nations having to pay a heavy price for it. A new effort must be made to clean up Lake Mjøsa,⁵ some restrictions on effluents must be tightened, but there is no real haste. Across the industrialized world, such evaluations of the situation are common. A public opinion poll would very likely show that the majority of the population shares Per Schreiner's views. Point 6 does not, however, primarily indicate a pessimistic view of the present situation, but rather an optimistic vision for the future. If changes come about as I conceive them, the quality of life will increase.

It is not given that it is necessary to change "fundamental" structures, even if the superior end of preserving the diversity of life on our globe must be accepted. It is not at all certain that the change of priorities that may be required will have to plow very deep.

(Erik Kåsa)

Point 6 was purposely vague, and the thirty-three respondents were free to interpret it in different ways, or to reject it as *too* vague. If what Erik Kåsa has in mind is freedom, equality, democracy, and the like, we do not have to *presuppose* changes. Nevertheless, a significant worsening of the ecological situation by a doubling or redoubling of the population might require that dictatorial measures be applied; alternatively, it might create chaotic circumstances in which the "right" of the stronger and more brutal prevails. The fundamental economic changes I have in mind will have to include a drastic strengthening of long-term priorities and a different understanding of the temporal perspective within which economic considera-

tions take place. The dominant maxim of “economic growth” must be eliminated or provided with a content drastically different from that associated with it now. New forms of communal life must be developed as fiscal, and other circumstances, be they by design or otherwise, make it difficult to breed more than two children.

I do agree that an improvement presupposes changes of attitude as pointed out in point 6. Whether these will be experienced as “delightful” by those affected, I am not quite sure. There is an inherent paradox in the fact that insofar as the enjoyment of a number of “goods,” like cars, holiday dwellings in the country, fishing as a sport, etc., is the privilege of a quite small group (“a privileged class”), there is no knowledge of the damaging effects. After the masses for generations have worked to achieve a standard of living that provides access to these same goods, rules are developed to bar them from realizing their goals. I am afraid that the realization of the conditions mentioned in the first sentence will constitute a rather painful endeavor.

(Kåre Kristiansen)

This is obviously an essential remark: a change in attitudes must in the first phase be presupposed to be most clearly developed among the economically best off. This concerns the use they make of their capital and their economic privileges. As long as they openly favor “goods” that only a few may obtain, the broader segments of the population will tend to believe that the use of such goods is particularly rewarding. They forget that conspicuous consumption will no longer be “conspicuous” once all take part in it.

My point on future gratification should have been omitted or modified. However, in some nonindustrial cultures, gratitude and joy in the sense of communion with nature has been a major topic. It is *possible* for us to reach such a distant goal.

It is an interesting feature of the answers to point 6 that they are brief. Kåre Kristiansen wrote the second longest one. It might be that the respondents consented to point 6 as a consequence of their consent to the preceding points. Many may also have found parts of point 6 unclear. Next is a response from Vidkun Hveding, which seems to have been reflected on thoroughly (as did his contributions to the debate on the Mardøla River regulation):

I do agree to the demands presented in the first sentence. With regard to the second sentence, “joyful experience” is a hopeful expectation that I share. The last part (on the dissolution of the motives that support the belief in the so-

called conquest of nature) I do not understand, even when considering the commentary on “the shallow movement.” For a human being like me, born and bred by nature, it is an incorporate orientation (“an imperative necessity”) to relate myself to nature in a way that secures the continuation of my existence. A tree, a fly, or a creek will not be “concerned” with my existence, but relate to me on their own conditions, if we meet. A “conquest” of nature then appears as senseless. Nevertheless, I do very well understand that a shortsighted “conquest of nature” may strike back terribly, and exactly in the sense sketched here.

Vidkun Hveding agrees on the conditions for a significant change. The assumption that a majority shares this view was the primary motive for conducting this investigation.

What Vidkun Hveding otherwise has to say perhaps testifies to an underestimation of the growing sense and understanding of our relations with all life. The “identification” that this increase provides for, makes it possible to see the experience of concern for other forms of life and the wholes that maintain them as *concern for oneself*. The concept of “self” that is implied in “my” self-realization is wider and deeper than the ego, which is considered in the popular versions of Darwinism. Technical and scientific insight today make it theoretically possible for a human population of reasonable size to live in a much more joyful and enlightened relationship with nature.

Responses to Point 7

My formulation of Point 7 was unsatisfactory. Forty-one words should perhaps suffice for achieving a higher level of precision? I considered myself obliged to suggest *something* about how the changes mentioned in point 6 would affect our lifestyle. The result was, unfortunately, the presentation of some slogans. I would have needed much more space to elucidate them in a sober and objective manner.

I find it very hard to respond to this question with a yes or a no, as it seems to me to be expressed very much in terms of what I consider slogans of the movement for environmental protection.⁶

(Per Harald Grue)

Many found themselves able to provide an answer despite these weaknesses:

Expert Views on the Inherent Value of Nature

To increase quality of life instead of the standard of living in this country is in harmony with my view. Yes, a reduction of the standard of living for large groups would be for the general good.

(Jon Tveit)

Agreed, but I presume that before a utopian attitude can develop, humanity must go through a time of distress, during which the consequences of the present development are recognized in all parts of the world.

(Per Oftedal)

Yes, in time, in our society. But how large a part of the world do we represent? What about the millions of hungry people, who do not merely live from one day to the next, but who also become ever more clear about the fact that we, in our part of the world, live in affluence at the expense of a slight increase in their standard of living? When will we start taking this problem seriously? When will we be forced to do so? Will we accept being forced, or will we take the matter into our own hands? Perhaps the pessimistic outlook on the future resides precisely in this question. It seems very hard to believe that a majority in our country will start reflecting on quality of life unless we, one way or the other, are awakened by someone from the outside forcing us to handle these matters differently.

(Bo Wingård)

I agree in part. But no matter how we twist and turn this matter, the question of the *means* will be central. I do not believe in any antitechnological romanticism in this context. The development can only move in one direction: farther ahead. All we can muster of science and technology must be geared toward new goals, e.g., to achieve a stable balance among different forms of life, instead of completing a "conquest of nature" (a particularly primitive goal).

(Ivar Øye)

This may be right in principle, but it is probably impossible to accomplish in practice. I suspect that I myself, as well as most other people, have an understanding of the quality of life that presupposes a highly developed technology, and therefore will be irreconcilable with ecological equilibrium.

(Erik Kåss)

A "highly developed technology" is to me today, however, one that does not have a dramatic impact on the material world and requires relatively few material resources for its employment compared to the satisfaction it provides.

I interpret what Erik Kåss expresses as a very important and honest

confession. Maybe “ecological equilibrium” can be achieved by combining changes both in how “most people” regard quality of life *and* in how they view advanced technology. Is it the opinion of Bo Wingård (see the quotation above) that some sort of equilibrium will appear, so to speak by itself, when the time is ripe? Will the situation, sooner or later, make most people recognize that materially defined luxury will not work whereas the technology I consider to be “highly” developed is exactly the one that contributes to an equilibrium? The way I see the situation, organizations such as The Future in Our Hands and Alternative North⁷ do essential work raising such questions, even if they are “ahead of their time.” Per Schreiner, as may be expected from his earlier responses, seems to mean that a relatively high material standard of living *and* equilibrium are possible, but *also* that we have much to learn from organizations like The Future in Our Hands:

I believe that large groups in the affluent Norwegian society still have their lives constrained because of material wants, including housing and child care. There is much that is valuable in The Future in Our Hands and Common Sense,⁸ much to learn about how more can be extracted from life under given conditions. My arguments would, nevertheless, depart from accepting that high material standards themselves are good, even if it is necessary to be aware of the cost of maintaining such standards because of the stress they produce both for oneself and for one’s surroundings, and through the strain they place on the natural environment. The last problems are perhaps the ones I would emphasize the least, because I am of the opinion that such problems to a large extent may be avoided at small material costs.

One response, the one presented by Finn Gran, may be distinguished from the others because it comments on the questions instead of answering them directly—except for point 8. I suppose that many of those who did not answer at all would have done likewise, if they had decided to answer. Therefore, I find it appropriate to quote some characteristic comments from Gran’s letter:

Regarding point 1:

Changes in the “climate” and the conditions of life on Earth have probably—usually slowly and sometimes quickly—been going on at all times. The whims of nature—and reflective as well as unreflective human action—have influenced natural values. Human beings must, I suppose, themselves be considered a part of “nature.”

Regarding point 3:

Human beings have by their “interventions,” e.g., through the development of a civilization, made it possible for you and me to *enjoy* nature in different ways. What would you have made out of your life by yourself, without the access to food, wine, proper housing, etc., produced by modern means? It is quite unthinkable to exist without access to such fundamental goods (tools) as, for example, energy.

Regarding point 7:

A high standard of living is in my view a condition for a good quality of life. Without an advanced economy, technology, medicine, etc., a happy birth, childhood, youth, old age, etc., are not possible. What goods are the “environmentalists” themselves willing to forsake? What about you, for example?

Regarding point 8:

Yes, and those who do not accept all your points nevertheless bear full responsibility for the welfare of the coming generations.

This article is not the right place to air my own thoughts in detail, but I am unable to restrain myself completely.

What worries many in Norway today, among other things, is the *kind* of *increase* in the average material standard of living since the mid-1950s. If we consider the needs for security, companionship, healthy nourishment, stable circumstances for family life, housing and proximity to the workplace, local community, and so on, the changes have, particularly in the 1970s, had little to do with an increase in the quality of life. The Future in Our Hands group has provided, and still provides, good answers to the question of how quality of life may be enhanced without stimulating the “consumerism” that today, to a large extent, is identified with high material standards of living. This consumerism is both unrealizable on a global scale and ecologically destructive. For these reasons alone it must be stopped.

Tens of thousands of Norwegians would gladly rest contented with a material standard of living that in many of its essentials would be no higher than it was during the Second World War occupation. Many more would “tolerate” a reduced consumption of material “goods” *if* the reduc-

tion were part of a plan for protecting Norwegian nature and increasing participation in global efforts to protect the conditions for life in general. The support for point 7 bears witness to a very serious dissatisfaction with our care for the diversity of nature; it also demonstrates an understanding of how difficult it will be to “turn the tide.”

The question of whether we in Norway today trade off the fundamental ends of life for perfecting technically interesting means is discussed by Vidkun Hveding:

I do agree to some extent. A real concern for ends must imply a certain interest in the means necessary for reaching them. What I agree about in particular is that the puritan industrial culture, which for a couple of centuries has provided a mighty push toward the fulfillment of some partial ends, has restricted our attention to the means at the expense of the ends to an extent that (no longer) is for the good.

It is impossible for me to leave point 7 without citing a contribution that I characterize as touching:

This I do agree about completely. . . . We have, however, only been able to live up to these goals in a rather helpless way, since the search for what we ourselves conceive as quality of life, in reality also is an egoistic endeavor.

(Olav Hilmar Iversen)

Neither the striving for a higher standard of living nor the striving for a better quality of life is in itself egoistic (in any reasonable interpretation of the word). Such striving may, however, become egoistic if not based on identification with other living beings. One who rejoices in the joy of others does not thereby become an egoist. Neither does one who, occasionally, deliberately seeks to please others in order to please himself. This “self” is not what in the terminology of social psychology is called the ego. (Please excuse me if this commentary sounds condescending!)

Responses to Point 8

How do we create a totally changed attitude in the population? This is the problem. How do we relate to the people of developing countries? They ought to have a higher standard of living, and it would not be bad if the cost is for us to lower ours. If and when this happens, their requirements will rise, and nat-

ural resources will become even more diminished. The world is complicated—in particular because there are human beings in it.

(Jon Tveit)

I agree with this, as a point of departure. Resourceful individuals have a particular responsibility for contributing to a more wholesome development of our societies, but this will not happen through the formation of societies such as *The Future in Our Hands* in which we speak to a limited congregation. The problem is how to make this way of thinking a natural part of life in our culture. Can we believe that our politicians may facilitate this, occupied as they are in fighting each other over what means to apply for furthering the common goal of growth and welfare? I do not think we must despair. I feel certain that those who are conscious of the responsibility will be given the opportunity when the time is ripe. . . . When will nature produce these thoughts with sufficient clarity for persons sufficiently competent to have a lasting influence on humanity?

(Bo Wingaard)

Let Jon Tveit and Bo Wingaard have the last words in the report on the answers to the eight points! Concerning the eighth point there was, as expected, broad agreement. I will therefore now quote miscellaneous comments of interest on topics not touched on directly in my eight points.

The main conclusion concerning the degree of agreement and disagreement is clear: there was general agreement on all eight points. Some of the points were vague enough to allow for diverse and equally vague responses. Therefore I cannot, with the exception of the responses to the central first part of point 6, sort the answers into clear-cut categories. In the summary shown in table 1, I distinguish among “clearly and definitely positive responses” (++), “positive rather than negative responses” (+), and “negative responses” (-).

Table 1: Summary of Survey Responses

	1a	1b	2	3	4	5	6a	7	8	Total:
++	25	20	24	17	24	26	26	16	28	206
+	1	4	3	6	0	5	5	1	2	27
-	1	0	0	0	0	0	2	0	0	3

A critic of my investigation, Peter Reed, has stated that my letter to these experts induced them to respond favorably. It seems highly unlikely,

however, that this influence could have been strong enough to reverse the ultimate outcome of the survey if the letter had been omitted.

Selected Topics

The Role of the Expert

On the responsibility mentioned under point 2, Per Sundby commented:

This responsibility is evident, but avoided like the plague by many “experts.” I have myself had the misfortune of experiencing both loss of confidence and professional scolding for presenting perspectives of value in a professional context and for commenting on “expert opinions” and/or “expert nihilism” concerning social problems and problems of health care.

It is perhaps unnecessary to mention that “presenting perspectives of value” is something I hoped to encourage by my letter. Something must be wrong, however, if “experts” who serve as advisers to public authorities are not “scolded” a bit from time to time in public debate. What will have happened if no such experiences are found?

The recognition that expert evaluations are neither all-encompassing nor quantitatively unambiguous often makes me ambivalent about my own role and my statements. As an expert, I believe that nuclear power plants may be built, that forests may be sprayed with weed killer, and so on. General social and political considerations nevertheless make me think that such power plants are undesirable (i.e., not because of the danger they represent but because of economic considerations, regional political concerns, antitechnocratic conviction, etc.). Similar considerations apply to the question of spraying with weed killer, although then my respect for the opposition of common people, their fears, romantic attitudes, etc., carries more weight. The simplest case is nuclear war, where all considerations point in the same direction. (As an “expert,” I have participated in an investigation of this question initiated by the World Health Organization.)

(Per Oftedal)

I hope that Per Oftedal, and others in similar positions, inform the public about their general attitudes even if these, at the deepest level, cannot be argued for on professional grounds.

If you, and others engaged in the environmental movement, are of the opinion that I am not eager to protect nature for its own sake, this may be an effect of my disapproval of speaking with professional authority outside of one's professional field. I have among my colleagues seen so many examples of "professorial" statements, which have been considered weighty merely because they were uttered by a professor, disregarding that he has been no more than a lightweight amateur in the relevant field. For this reason, I seldom express my opinions on topics other than those I have knowledge of as an "expert."

(Morten Gautvik)

I am tempted to say, That will not do, Mr. Colleague! The interested public ought to be informed about your priorities on questions of value, and your attitudes on questions of lifestyle. Neither can nor should your opinions as an expert be divorced from their general philosophical premises.

As an expert engaged in taking care of work that our society requires, I often feel unjustly attacked by the environmental movement, and I believe this has been harmful for the movement itself. If the matter was considered in a broader perspective, I am of the opinion that we to a large extent share the same goals, and that we to a larger extent ought to have worked together, rather than against one another, to reach it.

(Jon Tveit)

In the Norwegian debate on environmental issues, which has been quite lopsided in focusing on the regulation of rivers, statements have been uttered on both sides that should have remained unsaid. On the deepest level, we all share the same goals. Both sides, however, ought to develop a more critical attitude toward society.

Environmentalists cannot in any way accept that maintaining a high quality of life in Norwegian society requires energy to be used in today's quantities. Therefore, we have to distinguish between energy use and energy need. The quality of life depends on satisfying needs, not on increasing energy use. There is no direct contradiction involved, if the expert working to maintain production on the one hand is also warning insistently and publicly against increasing production on the other. The level of consumption in Norway today cannot be shared by all without producing terrible effects globally. Personally, I must add that I do not believe that the three kinds of goals in life—pleasure, happiness, and perfection—can be

achieved more easily with support from the overly complex apparatus that justifies the high level of energy consumption that we have today, than with the use of simpler tools. I do not know of any philosophy that claims that the achievement of a versatile and rich life requires the employment of complex means. From this conclusion stems today's deeply critical attitude toward industrial society.

This deeply critical attitude is, however, probably not shared by a majority of the 110 experts who received my letter. It is possible that many of those who did not answer share an attitude of the kind that Oluf C. Müller describes:

Guided by goodwill and common sense, my intuition tells me that, by and large, we achieve sound results from our work in this country. This is the case not the least because the so-called experts also have a sense for more than material values.

I am sorry to say that I am unable to display a correct picture of my attitudes [on the man-nature relationship] by answering the eight questions posed.

I believe that, at bottom, I am as fond of nature and concerned about it and the preservation of its different species as most people in our country. I judge it as very valuable that movements for environmental protection, and a general concern for environmental problems, have appeared. On the other hand, I have little sympathy for extreme responses—e.g., protesting professors employing direct action⁹—because I really believe this leads to the opposite of the desired results.

I am clearly a proponent for continued economic growth, although, of course, not at any price. The evaluation of the price is precisely what I am concretely confronted with, and this requires a sense of the appropriate in each different case, which cannot be described by answering the eight questions posed.

It has not been my intention to lecture. However, since lecturing has been alluded to, I have to admit that since I consider wonder not merely the point of departure for philosophy (Plato?) but also its point of arrival (hardly Plato's?), all definite opinions will have to seem unsatisfactory. There is little reason to believe that our "experts" at bottom feel very differently. A valuable response has the following postscript attached, reflecting on itself:

Puh . . . And how shallow, stupid, disconnected, and self-contradictory, despite revisions—which ought to have been pursued. Principles and generalizations are of interest.

(Hans Chr. Ødegaard)

***Basic Views on Value Are Neither Less nor More Justifiable
Than Basic Rules of Logic and Science***

I have little faith in absolute objectivity, and consider it both important and correct that common people see those who play the role of experts as human beings with personal values and convictions. I do not see in this any conflict with the respect for logical and disciplined thought.

(Per Schreiner)

From a philosophical point of view it is commendable that most respondents did consent to wide-ranging statements on values and norms. There were, nevertheless, signs of discomfort expressed in this agreement. How many statements on values and norms (ethical and others) be grounded? Can they be grounded rationally? Should not experts stick to statements that can be grounded rationally?

In what follows, I attempt (in a very simplified manner, if considered from a professional philosophical point of view) to calm the distrust regarding forcefully expressed statements on values and norms. There is little point in reducing such statements to a mumble or persistently employing phrases that reduce their force (“This I consider . . .” or “This I feel . . .”). What is required is a certain kind of basic respect for fellow human beings who proclaim opinions incompatible with one’s own. Stop mumbling, stand up, and proclaim your view!

Per Sundby’s comments on point 3 are in this vein:

Personally, I find it difficult to understand what rights men have or do not have, without a presentation of the reasons that justify norms limiting the rights of human beings in their relations with one another as well as in their relations with nature. I have been working to create a rational grounding of certain norms for consumption and norms for human relations that are important for the protection of health and welfare, and have collected extensive empirical material for this purpose. I am not certain that the same kind of rational grounding may be found for presenting the diversity of life as a precondition for human diversity, and particularly as a precondition for social stability and for the restriction of the space within which the most destructive forces can unfold. I am still looking for a way to bridge the gap between motives for environmental protection and the motive of preventing a continued deprivation of the health and social circumstances in different populations.

In certain formulations, (implicit) statements of value expressing the

rights of man seem to appear as the deepest level of justification. A deeper level would provide a justification for such rights of man. Let us assume that these rights are grounded in man himself as a rational being, or by the creation of man in the image of God. An even deeper justification would provide a normative grounding for one or both of these statements. The work on justification will continue indefinitely, unless statements are found at some level that can be claimed as self-evidently valid. Much philosophy has been developed to distinguish between what has been counted as self-evident before and what counts as self-evident now. This is very difficult terrain.

What I want to emphasize is merely that we have to *stop* somewhere. We present something as the deepest level in the chain of reasoning that provides justification for our opinions. We do not attempt to justify statements on this level.

The expression “rational grounding” of *A* by *B* is usually employed when *A* appears as more or less strictly implied by *B*, which then is accepted as the deepest level in the chain of reasoning. If the statement *B* is not accepted as valid, we accept that *A* is no longer rationally grounded in *B*. “Rational grounding” rests on statements that in logical terms are considered postulates *and cannot be grounded themselves*.

“Protect Norwegian health!” and “Protect Norwegian welfare!” are well suited in Norway as statements at the deepest level in chains of reasoning intended to aid social and political decisions. These may then be expressed as resting on rational grounds, but the rationality of this grounding is, of course, relative to the postulated imperatives.

Chains of reasoning either have an end or form a circle. In the latter case, we ground *A* in *B*, *B* in *C*, and *C* in *A*. I cannot accept such a procedure in full earnest and therefore contend that we have to accept that at any particular time, and in any particular situation, there is a deepest level of reasoning that is not grounded. This is the case both when “facts” are considered and when evaluations of values and norms such as ethical imperatives, rules of logical inference, and so on, are made.

Some answers clearly showed that taking a stand comes naturally. Per Sundby, and most of the other respondents, does not seem to have doubted the legitimacy of presenting strong statements in matters of value. On points 5 and 6, Sundby proclaims:

I have no difficulty supporting these views, even if they should lead into deep waters regarding evidence, objectivity, or professional respectability.

When we close in on the most fundamental premises, we are not in deep waters. We simply are.

Conclusion

The results of my investigation suggest that many of those close to the policy-making process consider changes to be necessary at all levels of society, politics, and ideology to protect the conditions of life locally and globally. They also indicate that at the grassroots level “experts” and “environmentalists” generally share a common view on what basic values ought to guide the effort to bring about such changes.

Given these insights, we should ask the “experts” why these values are so poorly represented in the practical policies that they participate in shaping. Finally, we should ask the “experts” how they believe this discrepancy between theory and practice can be bridged.

A heartfelt thanks goes to those who found time to answer my many questions, and to Kjell-Håvard Bråten, who aided me in the publication of the original text.

Appendix: List of Respondents

Fredrik Barth. Professor, Department and Museum of Anthropology, Ethnographic Museum, University of Oslo.

Trond Berg. Professor, Nordic College of Domestic Economics, University of Oslo.

Trygve Bergland. Former Department Director, Norwegian Water Resources and Energy Administration.

Anders Bratholm. Professor, Department of Criminology and Criminal Law, University of Oslo.

Knut Dæhlin. Director General, Ministry of Oil and Energy.

Odd Steffen Dahlgård. Professor, Clinic for Psychiatry, Ullevål University Hospital.

Torstein Eckhoff. Professor, Department of Public Law, University of Oslo.

Morten Gautvik. Professor, Department of Medical Biochemistry, University of Oslo.

VALUES, LIFESTYLE, AND SUSTAINABILITY

Tore Gjerløw. Head of Division, Ministry of Oil and Energy.

Finn Gran. Department Director, Norwegian Water Resources and Energy Administration.

Per Harald Grue. Director, Department of Agricultural Policy, Ministry of Agriculture.

Vidkun Hveding. Former Chief Executive Director, Norwegian Water Resources and Energy Administration.

Olav Hilmar Iversen. Professor, Institute of Pathology, University of Oslo.

Erik Kaas. Director of Administration, Oslo Sanitetsforening Rheumatism Hospital.

Kåre Kristiansen. Minister, Ministry of Oil and Energy.

Oluf C. Müller. Secretary General, Department of Industry.

Kaare R. Norum. Professor, Nordic College of Domestic Economics, University of Oslo.

Hans Chr. Ødegaard. Head of Division, Ministry of Agriculture.

Per Oftedal. Professor, Institute of General Genetics, University of Oslo.

Jan Økland. Professor, Division of Limnology, Department of Biology, University of Oslo.

Ivar Øye. Professor, Department of Pharmacology, University of Oslo.

Eystein Paasche. Professor, Division of Marine Botany, Department of Biology, University of Oslo.

Hugo R. Parr. Head of Technical Laboratories, Det Norske Veritas.

Alexander Pihl. Professor, Institute for Cancer Research, The Norwegian Radium Hospital.

Jan J. Qvigstad. Assistant Director, The Bank of Norway.

Roar Rognes. (position unknown)

Olav Sandvik. Director, Department of Agricultural Policy, Ministry of Agriculture.

Per Schreiner. Director General, Ministry of Industry.

Per Sundby. Professor, Institute for Social Medicine, University of Oslo.

Jon Tveit. Department Director, Norwegian Water Resources and Energy Administration.

Jon Rasmus Vale. Professor, Department of Thoracic Medicine, The National Hospital of Norway.

Olav Vannebo. Head of Division, Ministry of Industry.

Bo Wingård. Managing Director, Norwegian Correspondence Institute.

Should We Try to Relieve Clear Cases of Suffering in Nature?

This essay addresses the empirical manifestations of life, not questions about the innermost essence of life, whatever that may be. Therefore, it does not discuss beliefs in the absence or presence of a definite trend toward ever “higher” life-forms. It just talks about what we see around us.

Aldo Leopold and many other dedicated protectors of nature seem to hold that nature as it evolves with its fabulous manifold is good in an ethical sense, not beyond ethical good or evil. At least this is my conclusion about Leopold’s opinion, if we accept the rather trivial proposition that if something is ethically wrong, it cannot be ethically good.

In *A Sand County Almanac, and Sketches Here and There* (1987), Leopold says: “A thing is right when it tends to preserve the integrity, stability and beauty of the ecosystem. It is wrong when it tends otherwise.”

Various interpretations are possible, some of which are not acceptable to me. These are interpretations such that the above formulation—let us call it the *L*-formulation or just *L*—furnishes a general criterion or definition of right and wrong in an ethical sense. I do not operate with any such general criterion or definition. Also, I am worried about the “thing.” If “a thing” is meant to connote something much wider than “an interaction of a human being with the rest of an ecosystem,” then over the centuries things would happen that according to *L* would be wrong: ecosystems come and go.

A reformulation of *L* such that I could accept it would read: “A decision has presumption in its favor if there is reason to assume that its implementation will tend to preserve—or at least not interfere with—the integrity, stability, and beauty of the set of ecosystems concerned. A decision

This article was reprinted with permission from *Pan Ecology* 6 (1991): 1–5.

has a presumption against it if there is reason to assume that its implementation might reduce the integrity, stability, or beauty of the set of ecosystems concerned." I write "set of ecosystems" instead of just ecosystem because any human interaction happens with a set of comprehensive systems of unequal scale—the largest today being the planetary system of the sun.

At least one distinguished ecologist, Ivar Mysterud, and a friend of the reindeer, thinks that even if there were an ecologically very innocent way of heavily reducing the population of a certain parasite that causes extreme pain to the reindeer, or of altering its habits, it should nevertheless *not* be carried out. The reason: it might disturb a relevant ecosystem. We know too little (the *docta ignorantia* of a field ecologist!). I agree that there is a presumption against it, but I disagree with his conclusion. The very prolonged, cruel sufferings of the reindeer count more. I am for radically reducing the population of the parasite even if it may be wrong according to *L*. If an ecosystem is dominated by pain-producing parasites, perhaps we might say its "beauty" diminishes? I am somewhat uncertain about how to interpret the term, and also about the possibility that human beings could preserve or enhance beauty by interfering.

Philosophically less important, but ecopolitically important: if an ecosystem has been radically disturbed or destroyed by human beings (for example, through deforestation) and a different ecosystem is created (for example, a desert), does *L* cover the new system? If "man-made" ecosystems are not covered by *L*, how is the European situation to be judged? Fairly old landscapes that are "man-made" in the sense of having been radically influenced by human beings a long time ago are now protected as "free nature." We try to preserve their present integrity, stability, and beauty, or we try to restore a former ecosystem considered to be more "natural," but partly because their "human" character has been forgotten.

In short, I feel a need to know about how *L* is applied in concrete cases.

Perhaps because of the problematic nature of all proposed criteria of goodness since the time of Socrates, I look with wonder at the efforts to find a nontautological supreme and general characteristic of goodness. Perseverance in the service of protecting nature, and support of the deep ecology movement, does not imply any definite opinion on questions of unconditional goodness of nature as a vast set of ecosystems—not even on whether the question of goodness is meaningful. In what follows, I shall fo-

cus on the darker side of free nature and how contemplation of this may influence one's choice of ultimate criteria of the goodness and badness of a case of interference.

The development of life on finite Earth clearly presupposes the process of dying. We must "accept" death, but the death of insensitive beings does not disturb us as much as the death of sensitive beings, and a quick, painless death does not disturb us as much as a slow, painful one. Sometimes the quick death is due to predators; sometimes the slow, agonizing death is a "natural" death of old age—but sometimes the opposite is the case.

Every day some animals become weak and ill and enter a process of dying that involves prolonged pain as far as we can judge from their behavior. When wild reindeer smell large carnivores like bears, wolves, or dogs, they run away quickly. Old and tired reindeer find it more and more exhausting to keep up with the others. The same holds of some of the young ones. If they are caught quickly by carnivores, they tend to get a rapid, merciful death and not a slow, "cruel" one. Some reindeer experience the latter. Having been badly attacked by a winged insect (*Cephenomyia trompe*), they may die very slowly from suffocation from the growing larvae in their noses.

I hope no such planet exists, but consider one where slow, painful death from parasitism is universal. How would we talk about nature on such a planet? What kind of book would Thoreau have written there?

The parasitology of mammals tells us about parasites that kill or maim in ways that elicit intense alarm, disgust, and great negative feelings in us. Evolution specialists tell us that such parasites are not among the most successful and highly developed ones, which thrive without inflicting intense suffering or death on their hosts.

This admission of the imperfection of some parasites does not console their victims, however. The situation is relevant in assessing the adequacy of unconditional positive, sometimes highly emotional utterances about nature. What do human beings do when witnessing animals in what they think is unnecessary and prolonged pain? Those who intensely identify with the victims try to rescue them, provided it is not too late and a practical way is seen. The rescue may involve merciful killing by human hands. Generalized, and made into a policy, rescue attempts would amount to an

attempt to reform nature. Not everybody studying the consequences of such a policy will accept it as desirable. Because it is totally out of our reach completely to eliminate prolonged extreme suffering, it is of no practical value to discuss its ethical status, but its existence makes *general* glorification of nature strange to many of us.

A main point under consideration is our ignorance of consequences. What if we had adequate knowledge? One answer: we never will have! I suppose, though, that we could have sufficient knowledge in particular cases. If adequate ecological knowledge were available, some of us would not hesitate to interfere on a large scale against intense and persistent pain.

The manifold of different cultures is a desideratum according to most supporters of the deep ecology movement, but in many of them some animals in culturally important situations are caused terrifying and persistent pain by human beings. There is a real difference between initiation rites of a culture causing pain and rites involving animals who cannot grasp the meaning of the pain inflicted on them. Their helplessness is of a higher order. My very tentative conclusion is that the cultures in question might be approached in a way that indirectly would cause a change of behavior toward those animals.

"Look at this exquisitely beautiful little creature! Look at the colors, the shapes, the impressive and beautiful contrast between the green surrounding and its own colors! How can we not bow down in awe? How can we human beings kill and destroy so much of beautiful nature!?"

This passionate utterance may have occurred when a nature-worshiper saw a ladybird beetle in action, without noticing that the beetle was systematically using her formidable jaws to pierce the bodies of small green aphids, eating her way through a stalk of them. If her behavior were filmed and enlarged and shown on a big screen, the same nature-worshiper would probably shudder.

The utterance "beautiful, lovable!" does sometimes, but not always, depend directly on a process of identification. If identification is strong, an utterance like "tragic, paralyzing, horrible" may be rather natural. Moreover, action will follow, completely spontaneously. The victim is rescued.

A “compassion priority norm” seems to collide with the point of view of Stephan Lackner in his very important book *Peaceable Nature*:

We have to accept life on its own terms. There are no others, at least none that apply to us. We have to talk about “good” or “bad” even while conscious of the obvious relativity of such valuations. “Good for whom?” we have to ask before every decision. The more general the applications of this “good,” the more desirable. The mounting scale of positive values would appear, consequently, like this: good for my own self, for my family, for my club, for my community, my ideological or religious group, for my province, nation, continent, for humanity, in ever widening circles. Only when we come to the most general aim—good for life—is relativity suspended, allowing us to envisage an obligatory good.

(Lackner 1984)

Can I know whether rescuing or not rescuing a living being from lasting, excruciating pain is “good for life” of the biosphere at large? I don’t know, and I decide to rescue anyhow.

For some philosophers, among them Peter Wessel Zapffe (Naess 1991e), the hypothesis that life is completely meaningless plays an important role; for others, hypotheses about definite cosmic goals are all. Lackner says that we “have to accept life on its own terms.” Some people, however, decide to quit life, basing their decisions on hypotheses about their own lives and their unwillingness to continue. One may have a norm saying that one *should* accept life on its own terms, whatever they are, but this is a norm that many of us feel depends on some fundamental premises: answers to the question “Why should we?” Must we be passive because insufferable pain is a genuine part of life?

What is the status in the work of Thoreau of compassion and interference to end prolonged suffering? It is a question that might throw light on his basic view of identification and the human–nature relationship. When he observes one ant fighting another, there is identification:

I saw that, though he was assiduously gnawing at the near foreleg of his enemy, having severed his remaining feeler, his own breast was all torn away, exposing what vitals he had there to the jaws of the black warrior, whose breast-plate was apparently too thick for him to pierce; and the dark carbuncles of the sufferer’s eyes shone with ferocity such as war only could excite. . . . I felt for the rest of

that day as if I had had my feelings excited and harrowed by witnessing the struggle, the ferocity and carnage, of a human battle before my door.

(Thoreau 1971: 230–31)

Just within the edge of the wood there, I see a small painted turtle on its back, with its head stretched out as if to turn over. Surprised by the sight, I stooped to investigate the cause. It drew in its head at once, but I noticed that its shell was partially empty. I could see through it from side to side as it lay, its entrails having been extracted through large openings just before the hind legs. . . . Such is Nature, who gave one creature a taste or yearning for another's entrails as its favorite tidbit!!

(Thoreau 1949: 345–46)

There is a certain neutrality in this attitude in spite of strong, but partial identification with sufferers. I do not see examples of Thoreau interfering “in nature.” It is as if Nature, by him written with a capital *N* in the above quotation, is something apart or that human beings are something apart. I do not know. Just because I am not apart, I interfere in certain situations no matter what abstract reflection tells me.

Ecosophy, in my variant, “T,” does not imply any “acceptance of life” independent of definite assumptions about life. It contains—among others—two hypothetical assumptions: (1) there are no structures of the universe such that living beings cannot reach the highest levels of realization of their potentialities; (2) there is no definite limit of development of symbiosis, using this term in a wide sense. The development of ecosystems is not such that the self-realization of a living being depends *necessarily* on the destruction of the potentialities of others.

Part of the motivation for developing Ecosophy T is a reaction against “cult of life” and “cult of nature” *whatever its manifestations*. It is also a reaction against a tendency to take as axiomatic that life—Life with a capital *L*—somehow exists independent of the behavior of living beings, and that nature—Nature with a capital *N*—somehow exists independent of what happens, manifests itself for all to see. Ecosophy T does explicitly and firmly reject human brutality, cynicism, oppression of the weak, and lust for “power over.”

The twentieth century has seen political developments in which completely amoral acceptance of power and strength has been justified based on

concepts of “nature red in tooth and claw.” If nature is dependent on brutality, and we are part of nature, why should we try to shun brutality? As Hitler once said: “We have to destroy the Polish intelligentsia. It may sound brutal, but it is in accordance with the laws of nature.” Brutality, racism, and other coercive phenomena have been defended in many ways, but one of them is by means of an unrestricted acceptance of *every* manifestation of life in nature.¹

A student of cultural anthropology may witness in a particular culture a case of extreme suffering, which he may consider completely unnecessary and easily avoidable. Yet he knows that if he uses his way of eliminating that suffering, he undermines the culture. The clash of norms is formidable; there is no easy way out. Whatever the decision, the goal would be, according to Ecosophy T, to relieve extreme suffering of the kind envisaged *within* the framework of the culture. As with animals, ignorance and misconception must be taken into account. A culture is not something static.

Whether we are dealing with cultural systems or with ecosystems, the problematics are in principle the same: we have to assess the consequences of interference, the short-term as well as the very long-term effects, and judge the effects in terms of a norm system. We *have to* reach conclusions based on glaring inadequacy of available empirical knowledge and a clear norm system.

The complexity of the web of life even within a cubic millimeter of soil is, and presumably will remain, indescribable, but if humanity does not destroy itself, our basis for concrete ecological decisions may increase immensely. Respect for the dignity of free nature and proper humility do not rule out planned interference on a greater scale, as long as the aim is a moderation of conditions of extreme and prolonged pain, human or non-human. Such pain eliminates the experience of a joyful reality. We are not justified in turning our backs, or closing our eyes, to extreme suffering.

The higher levels of self-realization of a mature being *require* with increasing urgency the assistance of any living being to realize its potentialities, and this inevitably actualizes the concern for the sufferers.

This kind of argument indicates part of the motivation for not placing a norm like “Richness and diversity of life!” as an ultimate norm. The ultimate guidelines must squarely face the extreme suffering in nature. The argument implies disturbing some manifestations of life; it implies interfer-

ence in natural processes—but highly selective interference and not necessarily on a large scale. Interference in nature today is excessive.²

The admission of the existence of extreme kinds of suffering in free nature does not in any way support highly influential “bellicose” views of nature as a whole. The most often quoted articulation of such a view is that of the poet Tennyson: “Man . . . who trusted God was love indeed / and love Creation’s final law / Though Nature, red in tooth and claw / With raven, shrieked against his creed. . . .” Darwin used his expression “the struggle for life” extensively, and the interpretation was quite natural that he mainly referred to the painful and deadly struggle against enemies. Kropotkin, early in the twentieth century in his seminal *Mutual Aid* (1955), objected, but the view that nature was *full* of cruel competition suited the extreme economic liberalism and colonialism of England as well as the bellicose nationalism of Germany. Today, popularizations of this theme are still found in the life sciences. The opposition is vigorous but less known to the general public.

The following six propositions I think are tenable:

1. Predation (of animals by animals) has played an important role in evolution but is not a necessary ingredient on the level of birds and mammals.
2. A very small portion of birds and mammals die through predation (5–10 percent).
3. Only a small part of the life of animals is adequately described by the expression “struggle for life” or “struggle against enemies.”
4. The fitness referred to in the phrase “survival of the fittest” does not in general refer to fitness in deadly struggle or cut-throat competition with others.
5. Many birds, such as flamingos, and mammals, such as koalas, rarely meet a violent death (not taking human and exotic, human-introduced predators into account).
6. In the long run and on the whole, the less the chance of getting killed, the fewer the number of descendants. There is no general pressure to have as many offspring as possible. (Having no natural enemies results in a natural birth-control tendency of having fewer pregnancies.)

Should We Try to Relieve Clear Cases of Suffering in Nature?

Even if these propositions are strongly confirmed by observation, it is not very strange for a twenty-four-hour stroll in free nature to result in many observations aptly but unprofessionally characterized as tragic, brutal, cruel, hideous, horrible, or detestable.

Accounts written by forerunners and contemporary supporters of the deep ecology movement rarely mention these encounters and observations. Why not? I think it is worth pondering that most supporters implicitly assume and strongly feel the existence of a creative principle essentially connected with life that more or less compels veneration—something akin to Spinoza's "God or Nature." It is, however, nature with capital N. Trying to communicate this essential creative aspect of life by dwelling on cruelty and pain would lead us astray. So we don't talk about it?

In Ecosophy T there is an ultimate norm "Self-realization!" and an ultimate hypothesis "The higher level of self-realization reached by a living being, the more further increase requires others to reach self-realization."³ In simple words, it is not a question of acceptance of any kind of life but of "live *and let live*!" Thanks to the capacities of the human brain, full realization of our potentialities—if there is any limit—cannot be anything like an ego trip but must be a joint venture with other beings, both human and nonhuman. The higher the level of realization, the more the realization is a joint venture, a Self-realization without loss of the individuality of each living being. We have sometimes the potentiality of relieving extreme suffering, human *and* nonhuman—and we make use of that privilege.

Sustainability! The Integral Approach

The Greek philosopher Diogenes of Sinope, or Diogenes in the Barrel, is well known because of his meeting with Alexander the Great. When Alexander, standing in front of Diogenes' barrel, asked him to express a wish, he is said simply to have answered, "Please stop blocking my sun!" Alexander could have granted him much more. He could have had gifts produced through great expenditures of energy and natural resources. Diogenes was active in the rich cultural life of Athens, but this did not require any gifts of that kind. Diogenes' solution to his housing problem was a nonverbal expression of a globally, regionally, and locally sustainable lifestyle, and his answer was a verbal suggestion of the same. Alexander was reminded of the ecologically innocent character of vital needs, and—let us not forget Diogenes' proverbial wit and joyful, spontaneous character—Alexander got a lesson in "rich life, simple means." It is said that most followers of Diogenes through the centuries have misunderstood him, taking him to be a proponent of a simple, not a rich, life.

The reason I mention Diogenes of Sinope is to remind you that classical Greek philosophy as well as philosophy in the Middle and Far East combined the verbal and the nonverbal. You were not a philosopher if you did not. Today, we still say that so-and-so is a philosopher and use the word for such a combination, but the intended range of philosophies seems small. Mostly people have in mind what the professionals call popular Stoicism, or, to give another example, popular Epicureanism. The very special form

This article was reprinted with permission from *Conservation of Biodiversity for Sustainable Development*, edited by O. T. Sandlund, K. Hindar, and A. H. D. Brown. (Oslo: Universitetsforlaget, 1992), 303–10.

of Western academic philosophy does not ask for a philosopher. No combination of theory and practice is called for. If it were, some of you would perhaps be called sustainers, practicing a philosophy that combines theories of biodiversity and sustainable development with an appropriate, or at least, intended appropriate, lifestyle. There is much talk about a “new” ethics of respect for life on Earth, but it does not focus on the lifestyle of those who emphatically agree. One strong reason for the neglect is the plain fact that the complication and structural density of modern society make it practically impossible to combine the consistent use of simple means with participation in social and political struggles.

Depressing? Yes, but we may allow ourselves to say that Diogenes in the Barrel went too far. Here I follow Aristotle in advocating “everything with (philosophical) moderation.” An Indian practicing philosopher perhaps also carried the concern for citizens’ self-sufficiency and equimindedness too far when he, old and satisfied with life (“enough is enough”), brought together some wood, started a fire, placed himself on top, and cremated himself (in conformity with a practice that caused deforestation in certain localities). Incidentally, yoga of some sort is part of most classical Indian philosophies. They integrated theory and practice.

Fortunately, there are possibilities for decreasing the unsustainability and ununiversalizability of the “average” lifestyles in economically rich countries without decreasing life quality. To exemplify such a decrease is a great aim for some who wish to be taken seriously in the present struggles.

Discussing various interpretations of the term *sustainable development*, we may start with the following formulation: There is sustainable development if, and only if, it ensures that it meets the vital needs of the present-day human population without compromising the ability of future generations to meet their own vital needs.¹ This formulation resembles those of the Brundtland Report, but there is a major difference: the substitution of *vital needs* for just *needs*. Lists of needs made by decision makers in the rich countries include items that clearly are exorbitant and ununiversalizable. Even the *desire and demand* for more parking space is generally talked about in terms of satisfaction of a *need*. Those often are placed in urban locations where children have had their precious playgrounds, or where people have long lived but cannot afford a car, or among those who are incapable of resisting destruction of their habitat.

Needs are accepted that, if met, exclude sustainable development in every acceptable sense. The term *vital*, although vague and ambiguous, is a good starting point for a critical approach to the term *need* in its relation to *demand* in the marketplace of the world's rich countries.

If we postulate that human beings have a special ethical obligation toward their fellows, that which serves the vital needs of humanity requires a kind of priority. This does not mean, however, that we have no serious obligations toward nonhuman beings, and classes and systems of such beings, culminating with obligations relative to the Earth as a whole. These obligations, though, are mainly negative: obligations related to destructive consequences of our exponentially increasing interference in the ecosystems.

As to the satisfaction of human vital needs, there are at present a substantial number of human beings living in a desperate state of poverty or oppression, which clearly prevents a minimum satisfaction of those needs. They live mostly in countries one may call poor, using an economic measuring rod, and the term *sustainable development* should there imply *sustainable economic progress*.

The implied task is gigantic considering that there may soon be twice as many people in the poor countries but not twice the area of cultivable land. Under similar circumstances, Europeans who immigrated to North and South America introduced vast unsustainability, including a decrease of human cultural diversity.

It marks a major victory for the global ecology movement that the World Commission for Environment and Development announces clearly that sustainable development unconditionally requires ecological sustainability. The consequences of this admission are far-reaching because ecological sustainability requires significant economic, technological, social, political, and cultural changes in most or all countries. Here I shall first dwell on a terminological consequence: the term *developing country* automatically implies "ecologically developed country."

If we retain the underdeveloped/developed terminology, we must therefore class all ecologically unsustainable countries as *underdeveloped* without need to add the adverb *ecologically*. It is implied by our terminology that these countries are underdeveloped. The richest industrial country is not a developed country if it is not in a process of ecologically sustainable development.

A revised terminology has already been introduced in Norway: "When will it rise from being underdeveloped to being a developing country?"

That is, when will the rate of unsustainability (globally measured) decrease in a stable way? My guess is that by the year 2020 this may well happen. As it is now, Norway, like the United States, has not turned the tide of pollution, energy consumption, and other variables that must be taken into account. Those who think this guess is rather pessimistic are likely to neglect our wide perspective: it is the global situation that counts, and we must take into consideration that in the years 2000, 2010, 2020, with an even bigger population and with economic growth in terms of GNP in the Second and Third worlds, the projected level of Norwegian pollution, growing energy consumption, and so on, cannot be tolerated. Talking about 2020, I have assumed that political ability to take ecological problems seriously will increase, but not in any revolutionary way. That would require a vast increase of active interest within the Norwegian population at large—many more sustainers!

One may hold that it is wiser to modify the old usage of *developed*. My point is only that there is ample ground, when we seem to encounter its old use in discussions, to ask what the terms are meant to express, and then strongly discourage any use that might support the old belief that the rich industrial nations are developed and somehow able to show the poor countries the way to development. This belief is still not uncommon within the power elites of the Second and Third worlds, I am afraid.

In the 1980s it was out of the question for a wide group of politicians to declare that life on Earth, or life in the Universe as a whole, has any value in itself apart from the rather narrow serving of human needs and interests. It was out of the question to declare that the richness and diversity of life is worthy also of being cared for for its own sake, in the sense that we feel it obvious to care for children for their own sake. Such thoughts could not have been incorporated into a report such as *Our Common Future* by the World Commission on Environment and Development (United Nations 1987). By now, only one country, New Zealand, can show a public document that affirms intrinsic value. If, within a few years, such an affirmation becomes commonplace, it will not make much difference in human practice, but it will *add to the force of argumentation* in favor of generous, wide sustainability. “You *said* it has intrinsic value! Why don’t you act accordingly?”

The formidable capacity of our brains makes it easy for us to “see ourselves in others,” not only in other human beings but in every living being.

Sometimes it is even easier to identify with certain animals than with certain human beings. Compassion, aided by the brain, is something that encompasses everything capable of pain. The interest, in a broad, easily understandable sense, of a tiny plant to live and blossom is obvious, and under suitable circumstances we act to serve this interest. The definition of sustainable development cannot ignore these facts. A wide and deep perspective is obviously needed. Human capacity to think and to feel, human dignity, requires it. Our contemplation of the development of life on Earth through countless millions of years, the development of the richness and diversity of life-forms, almost inevitably makes mature, informed human beings adopt a wide perspective. In short, we demand that full ecological sustainability shall mean or include conservation of the richness and diversity of life-forms. We cannot slavishly accept the narrow interpretations of the Brundtland Report (*ibid.*), interpretations that some of the signatories, including Gro Harlem Brundtland herself, personally, I think, find too narrow.

Let us look closely at the term *sustainable development* as it occurs on page 8 of *Our Common Future* (*ibid.*): “Humanity has the ability to make development sustainable—to ensure that it meets the needs for the present without compromising the ability of future generations to meet their own needs.” Plausibly, but narrowly interpreted, what might according to the above be considered satisfactorily sustainable is compatible with maximal destruction of life conditions on Earth, a maximum of extinction of life-forms and habitats of life-forms, a maximum of gross human interference with landscapes and ecosystems—as far as these maxima are conceived to allow satisfaction of human needs, as those needs are conceived at any definite time. In addition, we must ask, Considered by whom? It is clear that by “reforestation” many decision makers do not refer to getting back real forests. The artificial tree plantations with fast-growing trees do not support the biodiversity of a forest. The number of species in them may be one-fourth, or less, of those of a decimated forest. If it is objected that one must distinguish the forest *itself* from the animal and plant life in it, the ignorance of ecosystem thinking is clear, and the way is open for a maximal destruction that only too late will be seen to be incompatible with the satisfaction of vital needs of additional billions of people born in the years to come.

In the present conflicts, the usual narrow interpretations of “sustainable development” are convenient for planners of gigantic destructive poli-

cies, because it is difficult to convince people that future generations will lack the ability to take care of themselves whatever we find suitable to do. People read about technological inventions, even revolutions, that are likely to push the limits of responsible growth indefinitely. They do not read about the lack of economic and political will to make global use of the inventions made even long ago.

Rejecting the narrow concepts of ecological sustainability, which a plausible interpretation of the Brundtland Report admits, some of us are on the outlook for definite, wider interpretations. Preferably these should not be completely implausible interpretations of the document but should be in harmony with what at least one of the twenty-two people underwriting the document had in mind. The criterion I am going to make use of in what follows does not explicitly refer to human beings, but they and the richness and diversity of their cultures are implied.

There is ecological sustainability if, and only if, the richness and diversity of life-forms is sustained.

Ecology helps us to understand and watch out for destruction of ecosystems and habitats. Those terms are not used in the above formulation because it should be widely understood and be emotionally attractive. By “richness” I do not refer to abundance of specimens of species but to their wide distribution locally and regionally, provided that wide distribution is realized today or was recently realized and it is practicable to restore the former situations.

The criterion is applicable to the Earth as a whole, to regions, nations, and societies, but only to some extent to localities. It is perhaps of little use to talk about ecological unsustainability, for example, in *small* areas or localities of monoculture or of city developments. A region may be called sustainable even if there are plenty of localities of that kind. Otherwise, sustainability is too utopian. The term *development*, however ambiguous, must be used because of its importance in policy documents. A terminology proposal:

A *development* is ecologically sustainable if and only if there is a long-term trend that assures, or that may justifiably be considered to assure, ecological sustainability.

The special obligations we have for our own species require us in the long run to assure a population what is necessary to provide conditions for

reaching the ultimate goals of humankind and satisfying vital needs. Beyond that, our obligations to life in general and the Earth as a whole acquire priority. These obligations will in the foreseeable future scarcely determine policies with wide sustainability as a goal. If the most exciting threats, such as those involving climatic change and the ozone layer, seem to be overcome, and if spectacular animals and limited plant biodiversity are saved, certain regions may be classed as developing in an ecologically sustainable way. In a broad sense, crude ecological unsustainability may still be at hand. There is a long way to go.

If some Third World countries reach ecological sustainability in the next century, which one will be the first? Costa Rica? The education level of women is high, the standard of living is increasing, the government is interested, a significant number of "parataxonomists" (raised in the country) and others help mapping out the fauna and flora and do an important job to increase respect for and joy of life. Furthermore, much is done to develop sustainable uses of tropical biodiversity, thus integrating concern for ecological sustainability in society. The cooperation of researchers and local people is flourishing. The ecologist Daniel H. Janzen is the most well-known researcher working along "social ecological" lines and collecting millions of dollars in aid for Costa Rican projects. All this activity decreases the ecological unsustainability in some ways, but large-scale deforestations still go on. Some researchers guess that only about 10 percent of the habitats will be saved from complete human domination with extensive regions of monocultures and asphalt. It is, therefore, a wide-open question when sustainability will be reached, if at all.

One may wish that all other tropical countries would develop in the auspicious way of Costa Rica. The corresponding amount of money that would have to be collected in the rich countries would not be in the range of millions, but billions. Benevolent bureaucracies would have to be available, and an army of ecologists and their assistants working together with the local populations.

The great Danish philosopher Søren Kierkegaard, the father of existentialism as a philosophical movement, insisted that human beings are always in "deep water." Their decisions must be made on the basis of a total integrated view, but systems like Hegel's are mere fictions. This implies, in principle, going back to ultimate premises, and to a conception of the main

goal of human life, whether pleasure, happiness, or achievement of some sort. It implies also that if you consider a certain question to be of immediate relevance for actions in your life, your community, or life on Earth, you must have an answer, whether expressed through deliberate words or through deeds. Moreover, we should remember that even if we do not answer deliberately, our actions or lack of actions express answers.

In life one cannot say “Leave me out!” Ignorance and incompetence furnish explanations, but not an excuse—not automatically. The question “Are we informed to an extent that should be expected of us?” is relevant.

Crudely expressed, if it is an important decision either to turn right or to turn left, to do neither also has important consequences. One answer may be “I am too tired to reflect. I’ll go left!” This or similar kinds of answers must, of course, sometimes be tolerated. The main thing is the awareness, with equanimity, that a choice is made anyhow.

The practicing philosopher is one who feels an obligation to answer but who does not thereby pretend that it is worthwhile for others to listen. Perhaps all our answers are more or less imperfect.

Those who are serious about somehow decreasing unsustainability locally, regionally, or globally may contribute to the effort in specialized jobs (for example, as researchers) or as generalists, showing as much as explaining their choices in life. They are then to be classed as *practicing philosophers*, whatever their degree of ignorance of academic philosophy. Sometimes this ignorance may be an advantage.

In our very special kind of culture in the rich countries of the West, verbal articulations in the form of reasons are highly appreciated. Somebody may ask, “What is your reason for valuing priority *A* over *B*?” You may have a reason R_1 , but then you are asked, “What is your reason for accepting R_1 as adequate?” Suppose you answer with an R_2 , or you admit that you do not pretend to have a sort of reason R_2 such that if it were untenable you would give up the priority of *A* over *B*. That is, you stop the chain $R_1, R_2, \dots R_n$, after the first number of the series. Generally speaking, such behavior is wise, because it is likely that sooner or later you will give misleading reasons, reasons that do not really fit your ultimate or complex motivation. Today, though, we must dig deeper—our global perspective makes it necessary.

One of the many great achievements of Aristotle was a clear denial that

we can prove everything we assert. We cannot give good reasons for everything. We stop somewhere, normally outside science, and doing this, we may, if appropriate, quote Aristotle. We can say that belief in the possibility of proving everything shows lack of education, and that we like to be considered educated.

My advice is to stop giving reasons when you announce something you personally find *intuitively* obviously true or correct, or something that you cannot imagine yourself giving up except for reasons you have never heard of and cannot see how they could be convincing. This is not dogmatism. You are not less philosophical or deep or scientific for stopping at a certain point to repeat again and again certain announcements without giving reasons. You are not worse off than mathematicians and logicians who repeatedly use the basic rules of inference, which they, by definition, cannot prove or validate scientifically.

Intuitively-based announcements are common today. Here are some examples:

“Every life-form has a worth of its own independent of its usefulness for human beings.”

“Animals have a right to exist, no less of a right than human beings.”

“Life diversity is a good thing independent of human usefulness.”

“Life on Earth is a value even without human beings to value it.”

Some philosophers offer reasons in favor of these pronouncements; others accept them without offering reasons; still others do not accept them and give reasons for that. They also stop giving reasons somewhere.

All this would be pointless to say except that, again and again, we see people who *unreasonably* feel guilty for not giving reasons, or we see scientists who hide or never announce their basic norms or evaluations because they lack “scientific” reasons.

Human beings are never wholly functionaries; they never behave wholly as functionaries. They are always, as specimens of adult, sane *Homo sapiens*, responsible as persons. The timid “As I see it . . .” and “In my personal opinion . . .” are misplaced if ultimate views are at stake. You try to step outside of yourself, try to be a *mere* witness to your own intuitions.

What about conflicting intuitions—are they not a cause of violence and war? Yes, but also a partial cause of peace, progress, and nonviolence of the most superb kind.

Some concluding remarks: Full global and regional biodiversity is necessary to reach full ecological sustainability. Full ecological sustainability is necessary to realize sustainable development. Biodiversity is required to satisfy the vital needs of humanity. This is now generally acknowledged. That the biodiversity of this planet should be protected also for its own sake was first internationally recognized through the United Nations World Charter for Nature. The initiative to get this established was taken by a group of Third World nations. The General Assembly adopted the charter in 1982 by a vote of 111 to 1, with the United States casting the sole dissenting vote. Only a *rich* nation dissented!

It serves the cause of biodiversity to maintain that it has a value in itself apart from narrowly conceived usefulness for human beings. It also helps when people who maintain this testify to its profound implications through their lifestyle, at least in some ways in some kinds of life situations.

High-level humanitarian norms justify ecologically negative policies. They should be short-range, and often they are avoidable by a cooperation of rich and poor nations on a greater scale than ever before.

Because of its touchy nature, I wish to end with a remark on the size of the human population as seen in a cultural-philosophical perspective: a future long-range, slow decrease of the human population would to some extent increase the chances of full biodiversity, sustainable development, deep cultural diversity, and the prospect of satisfying vital needs and reaching cultural and philosophical goals.

The Arrogance of Antihumanism

One may have such a low opinion of the human race that the phrase “live and let live,” applied to the ecosphere as a whole, is considered incompatible with deep, specific human interests. Permit me to suggest that the attitude expressed by “live and let live,” in the broadest and deepest sense, is specific to human beings. Up to this point, we know of no other life-form in the universe whose nature is such that, under favorable circumstances, it would more or less inevitably develop a broad and deep concern for life conditions in general.

Human beings have a sufficient natural endowment such that they can perceive and enjoy their kinship with living beings of the most diverse kinds, and care for them. To realize their total potentialities, mature human beings need communities that permit them to live out their full capacities for identification with other life-forms.

Under unfavorable social conditions, human capacities for identification do not manifest themselves. There is, however, sufficient empirical evidence to show that people in our industrial societies who are reared and educated under appropriate conditions do develop attitudes of the kind expressed in deep ecology. This occurs without their being necessarily deficient or immature in other human ways.

If we focus our attention unduly on the crudest behavior of human beings, we are tempted to form an unfavorable image of human nature. This focus tends to lead some authors to postulate that the domination and exploitation of nature are inherent in the nature of human beings, that the

This article was reprinted with permission from *Ecophilosophy* VI, edited by George Sessions (May 1984): 8–9.

primacy of human interests implies the subjugation of the interests of other beings.

On this planet only human beings formulate general norms about equal rights, and perhaps only human beings have a nature that calls for identification with all life-forms. This makes it awkward to use the term *humanism* to refer to attitudes that go against human nature in a philosophical sense. Present-day anthropocentrism is inhuman in my view. It is specifically human both to see and formulate the limitations for the role of human beings in the ecosphere and to experience their identification with the whole.

In criticizing the “homocentrism” or “anthropocentrism” of the shallow ecological movement, we are pointing to an image of man as an immature being with crude, narrow, shortsighted interests. It is an image well suited to the kind of policies that predominate today. I refuse to accept the view that a high level of human self-realization can be reached by the satisfaction of mere narrow, insensitive, shortsighted interests.

“Obviously the most humane goal of mankind is the improvement of the human lot” (Watson and Smith 1970: 25). Yes and no! Yes, only if “human lot” is defined in harmony with the need to satisfy basic aspirations such as the realization of egalitarianism as defined below. Then the quoted sentence does not say much more than this: . . . given a set of value priorities for humankind. In relation to such a set, the most humane goal is the improvement of conditions for realizing the priorities.

If “human lot” is defined more narrowly, then something will be missing. Then we would have to add “But surely it is just as specifically a humane goal to improve the lot of a broader class of beings!” This holds even if we admit that the fight for mere biological survival must sometimes considerably narrow down our goals. Such temporary minimum goals, however, are not the most humane.

Human beings have no less right than any other life-form to change the world. I do not see that deep ecology needs a *general* norm against human efforts to change ecological conditions on Earth, but Barry Commoner and others are right about the present-day generation of human beings when they claim that any major man-made change in natural systems is “likely to be detrimental” to those systems. Today’s combination of ignorance, arrogance, and narrow perspective justifies this pessimistic view. If, however, human beings in some remote future could avert a glacial age, or

the impact of a comet, then I tend to think that no norm should be used against interference of this magnitude in natural systems.

Egalitarianism applies to human beings: they have the right to live and blossom, *just as* other life-forms do. This right is in principle the same and does not admit of degrees. (The term *egalitarianism* should perhaps not be used for this equalness, for it is also used in many other conflicting ways.) Each life-form has its own nature, which determines what kind of life gives maximum satisfaction. For example, among bears there are differences in lifestyle (some bears not only kill for food but also maim and cripple).

It may sound paradoxical, but with a more lofty image of maturity in human beings, the appeal to serve deep, specifically *human* interests is in full harmony with the norms of deep ecology. This is evident, though, only if we are careful to make our terminology clear. This terminology is today far from common, but it may have an illuminating impact. It proclaims that essentially there is at present a sorry underestimation of the potentialities of the human species. Our species is not destined to be the scourge of the Earth. If it is bound to be anything, perhaps it is to be the conscious, and joyful, appreciator of this planet as an even greater whole in its immense richness. This may be its “evolutionary potential” or an ineradicable part of it.

Is today’s large-scale deforestation “natural” for human beings? It depends on our terminology. In my terminology: no. There are others, though, who seem to think that a norm against destruction would thwart the human species in “its natural behavior” (Richard A. Watson). If we are to refer to how human beings actually have behaved lately: YES. Why not adopt a kind of terminology with deep roots in the past, the *kata-physin* terminology. To live “according to nature” is for human beings not just to live without any bearings.

It is deemed natural for a species to show preference for its own interests over the interests of any other species. In a society that fulfills human aspirations, the mature member shows preference for its interests over the interest of any *single* other species, but only because human interests concern greater wholes in space and time. The mature member is a friend of the Earth. Their deepest interests are not destructive.

If someone asks how I know this, my answer is that, of course, I do not know this—but neither do they who would maintain that mature human interests constitute a threat.

The Place of Joy in a World of Fact

The solution of environmental problems is presupposed in all utopias. For example, every family is to enjoy free nature under Marxian communism. “In a communist society,” Marx says in a famous passage in *The German Ideology* (1970), “nobody has one exclusive sphere of activity but each can be accomplished in any branch he wishes. Society regulates the general production and thus makes it possible for me to do one thing today and another tomorrow: to hunt in the morning, fish in the afternoon, tend cattle in the evening, engage in literary criticism after dinner, just as I have in mind, without ever becoming a hunter, fisherman, shepherd, or critic.”

The complete individual is not a specialist; he is a generalist and an amateur. This does not mean that he has no special interests, that he never works hard, that he does not partake in the life of the community. He does so, however, from personal inclination, with joy, and within the framework of his value priorities.

In the future ideal society, whether outlined by Marx or by more bourgeois prophets, there will be people who might use most of their energy doing highly specialized, difficult things, but as amateurs—that is, from inclination and from a mature philosophy of life. There will be no fragmentary men and women, and certainly no fragmentary ecologists.

We all, I suppose, admire the pioneers who, through endless meetings held in contaminated city air, have succeeded in establishing wilderness ar-

This article was reprinted with permission from *Deep Ecology for the 21st Century: Readings on the Philosophy and Practice of the New Environmentalism*, edited by George Sessions (Boston: Shambhala Publications, Inc., 1995), 249–58. It was originally published in *The North American Review* (Summer 1973).

eas in the United States. Unfortunately, their constant work in offices and corridors has largely ruined their capacity to enjoy these wilderness areas. They have lost the capacity to show, *in action*, what they care for; otherwise, they would spend much more time (and even live) in the wilderness. Many people verbally admire wilderness areas, but they have not stepped down from their exalted positions, as chairmen of this or that, to enjoy these areas at least part of the year.

What I say here about advocates of wilderness seems, unhappily, to be valid for advocates of a better environment in general. Ordinary people show a good deal of skepticism toward verbally declared values that are not expressed in the lifestyle of the propagandist. Environmentalists sometimes succumb to a joyless life that belies their concern for a better environment. This cult of dissatisfaction is apt to add to the already fairly advanced joylessness we find among socially responsible, successful people, and to undermine one of the chief presuppositions of the ecological movement: that joy is related to the environment, and to nature.

In short, the best way to promote a good cause is to provide a good example. One ought not be afraid that the example will go unnoticed. For example, Albert Schweitzer hid himself in Africa, but his public relations prospered and so did the sale of his books.

So much for utopias. My next concern is with how to get nearer to our utopias. I shall take up only one aspect: the relation between personal lifestyle and teaching.

The Lifestyle of Environmentalists

Joy is contagious. If we only talk about the joys of a good environment, though, it is of little avail.

I know that many *have* turned their backs on more lucrative careers and on a life of security cultivating well-established sciences. This is not enough, however. Life should manifest the peaks of our value priorities. Working for a better environment is, after all, only of instrumental value. We remain on the level of techniques. What criterion shall we use to follow the lead of our personal priorities? We do have one that is underrated among conscientious, responsible people: joy.

Joy According to “Pessimistic” Philosophers

Suppose someone openly adhered to the doctrine that there cannot be too much cheerfulness under any circumstances—even at a funeral. The sad truth is, I think, that he or she would be classified as shallow, cynical, disrespectful, irreligious, or mocking.

Søren Kierkegaard is an important figure here. He *seems* to take anguish, desperation, a sense of guilt, and suffering as the necessary, and sometimes even sufficient, condition of authentic living, but he also insists upon continuous joy as a condition of living. Whatever is done without joy is of no avail. “At seventy thousand fathoms depth,” you should be glad. At seventy thousand fathoms, one should retain “a joyful mind.” He sometimes calls himself Hilarius, the one permeated with *hilaritas* (the Latin word for cheerfulness).

Dread is the technical existentialist word for the kind of anxiety that opens the way to a deeper understanding of life. According to Heidegger (another hero of modern pessimism), dread is not an isolated sensation of a negative kind. The mind is in a complex state in which dread cannot exist without joy; that is, one who thinks he has the dread experience but lacks joy, suffers from an illusion. Dread has an internal relation to joy.

Our problem is not that we lack high levels of integration (that is, that we are immature and therefore joyless) but rather that we glorify immaturity. Do the most influential philosophers of our time and culture represent high degrees of maturity and integration? I have in mind not only Heidegger, Sartre, Kierkegaard, and Wittgenstein, but also Marx and Nietzsche. Tentatively, I must answer no. There are lesser known but perhaps more mature philosophers, like Jaspers and Whitehead.

Should the world’s misery and the approaching ecocatastrophe make one sad? My point is that there is no good reason to feel sad about all this. According to the philosophies I am defending, such regret is a sign of immaturity; the immaturity of unconquered passiveness and lack of integration.

The remedy (or psychotherapy) against sadness caused by the world’s misery is to do something about it. I shall refrain from mentioning Florence Nightingale, but let me note that Gandhi loved to care for, wash, and massage lepers; he simply enjoyed it. It is very common to find those who

constantly deal with extreme misery to be more than usually cheerful. According to Spinoza, the power of an individual is infinitely small compared with that of the entire universe, so we must not expect to save the whole world. The main point—which is built into the basic conceptual framework of Spinoza's philosophy—is that of activeness. By interacting with extreme misery, one gains cheerfulness. This interaction need not be direct. Most of us can do more in indirect ways by using our privileged positions in rich societies.

There are clear reasons for us not to concentrate all our efforts directly on extreme miseries, but rather to attack the causes, conditions, and factors indirectly contributing to this misery and, just as important, to encourage the factors that directly cause or facilitate the emergence of active (and therefore cheerful) work to alleviate misery.

Behind the prevailing widespread passivity found throughout the world is a lot of despair and pessimism concerning our capacity to have a good time. We tend to enjoy ourselves (except during vacations) in a private world of thoughtlessness, well insulated from the great issues of the day.

One of the strangest and next-to-paradoxical theses of Spinoza (and of Thomas Aquinas and others) is that knowledge of evil, or of misery, is inadequate knowledge. In short, there is no such object, whereas there is something good to know. Evil is always an absence of something, a lack of something positive. Their theory of knowledge holds that objects of knowledge are always something. When you say that you see that the glass is transparent, what you see, for example, is a red rose behind the glass. You do not see the transparency, which is not an object of perception.

In any event, while I do not think that the positive nonexistence of evil things can be shown without a great deal of redefinition of words, I nevertheless do not consider this view totally ridiculous. Like so many other strange points of view in major philosophies, it has an appeal and points in the right direction without perhaps stating anything clearly in the “scientific” sense.

Spinoza on Joy

Spinoza operates with three main concepts of joy and three of sorrow. *Laetitia*, *hilaritas*, and *titillatio* are the three Latin terms for the positive emo-

tions of joy. Translations of these terms are, to a surprising degree, arbitrary, because their function in Spinoza's system can be discovered only by studying the complex total structure of his system. Isolating one concept from the others is not possible. Moreover, the system is more than the sum of its parts. From a strict, professional point of view, you must take it or leave it as a whole.

I translate *laetitia* as "joy"—a generic term comprising several important subkinds of joy. The main classification of joy is into *hilaritas* (cheerfulness) and *titillatio* (pleasurable excitement). *Hilaritas* is the serene thing, coloring the whole personality, or better, the whole world.

Spinoza defines *hilaritas* (cheerfulness) as a joy to which every part of the body contributes. It does not affect just a subgroup of functions of the organism, but each and every one, and therefore the totality of the organism. Spinoza contends that there cannot be too much of *hilaritas*.

The other main kind of joy, *titillatio*, affects a subgroup of the parts of the body. If very narrowly based and strong, it dominates and thereby inhibits the other kinds of joy. Accordingly, there can be too much of it. Here Spinoza mentions love of money, sexual infatuation, and ambition. He also mentions other sources of joy that are all good in moderate degrees if they do not hamper and inhibit one another.

A second classification of joy is that derived from contemplation of our own achievement, creativity, or—more broadly—activeness, and the joy derived from contemplation of causes of joy outside of us. The first he calls satisfaction, or repose in ourselves (*acquiescentia in se ipso*); the other he calls *amor*. There can be too much of them, however, because they sometimes refer to parts, not to the whole.

According to Spinoza, what refers to the whole of the body also refers to the whole of the conscious mind, and to the whole of the universe or, more generally, to the whole of Nature, insofar as we know it. This is understandable from Spinoza's so-called philosophy of identity, which proclaims the ultimate identity of thought and matter, and from his theory of knowledge, which relates all our knowledge of the world to interaction with the body—just as biologists tend to do today.

Lack of self-acceptance (*acquiescentia in se ipso*) accounts for much of the passivity displayed by an important sector of the public in environmental conflicts. Many people are on the right side, but few stand up in public

meetings and state how they, as private citizens, feel about the pollution in their neighborhoods. They do not have sufficient self-respect, respect for their own feelings, and faith in their own importance. They themselves do not have to fight for the changes; it is only necessary that they state their feelings and positions in public. A small minority will then fight with joy—supported by that considerable sector of people.

The distinction between pervasive joy (covering all) and partial joy need not be considered an absolute dichotomy but rather exists in degrees. Joy may be more or less pervasive. Clearly, higher degrees of joy require high degrees of integration of the personality, and high degrees of such integration require intense cultivation of the personal aspect of interaction with the environment. It requires a firm grasp of what we call value priorities—which Spinoza would call reality priorities, because of his resolute location of value among “objective” realities. Spinoza distinguishes degrees of realness and perfection. That which is perfect is complete. Integration of personality presupposes that we never act as mere functionaries or specialists but always as whole personalities conscious of our value priorities, and of the need to manifest those priorities in social direct action.

The specific thing to be learned from Spinoza and certain modern psychologists is, however, to integrate the value priorities themselves in the world. We tend to say “the world of facts,” but the separation of value from facts is, itself, mainly due to an overestimation of certain scientific traditions stemming from Galileo, traditions that confuse the *instrumental* excellence of the mechanistic worldview with its properties as a whole philosophy. Spinoza was heavily influenced by mechanical models of matter, but he did not extend them to cover “reality.” His reality was neither mechanical, value-neutral, nor value-empty.

This cleavage into two worlds—the world of fact and the world of values—can theoretically be overcome by placing, as Spinoza does, joys and other so-called subjective phenomena into a unified total field of realities. This, however, is too much to go into here. I am more concerned with the place of joy among our total experiences. The objectivist conception of value is important, though, in any discussion in which technocrats tend to dismiss cheerfulness in the environment as something “merely subjective.”

Spinoza makes use of the following short, crisp, and paradoxical definition of joy (*laetitia*): "Joy is man's transition from lesser to greater perfection." Somewhat less categorically, he sometimes says that joy is the affect by which, or through which, we make the transition to greater perfection. Instead of "perfection" we may say "integrity" or "wholeness."

Of central importance, in my view, is the difference between these formulations and subjectivistic ones proclaiming that joy only *follows* or *accompanies* these transitions to greater perfection. For Spinoza the relation between joy and an increase in perfection is an *intrinsic* one. That is, the two can be separated only conceptually, not in practice. Such a realistic view of joy suggests that joyfulness, like color, attaches to and forms part of objects, but of course changes with the medium, and must be defined in terms of interaction with organisms. Joy is linked intrinsically to an increase in perfection, an increase in power and virtue, an increase in freedom and rationality, an increase of activeness, an increase in the degree to which we are the cause of our own actions, and an increase in the degree to which our actions are understandable by reference to ourselves. Joy is thus a basic part of the conceptual structure of Spinoza's system.

An increase in power is an increase in the ability to carry out what we sincerely strive to do. Power does not presuppose that we coerce other people; a tyrant may be less powerful than some poor soul sitting in prison. This concept of power has a long tradition and should not be forgotten. What we strive to do is defined in relation to what actually happens; thus "to save the world from pollution" is not something anyone strives to do, but is rather a kind of limited effort to save the things around us.

Cheerfulness (*bilaritas*) requires action of the whole integrated personality and is linked to a great increase in power. In the absence of joy, there is no increase of power, freedom, or self-determination. Thus, lack of joy should be taken seriously, especially among so-called responsible people furthering a good cause. The joy of work, like any other partial joy, can dominate and subdue other sources of joy to such an extent that the overall result is stagnation or even a decrease in power. In Spinoza's terminology, this means a loss of perfection or integration, and increased difficulty in reaching a state of cheerfulness.

"To be happy" is often equated with enjoying oneself, laughing, or

relaxing in the sense of being passive. Enjoying oneself by becoming intoxicated, which decreases the higher integrations of the nervous system, results in resignation. It means giving up the possibility of joyfulness of the whole person. Cheerfulness, in the Spinozistic sense, may not always be expressed in laughter or smiling, but in concentration, presentness, activeness.

The example of Buddha may illustrate my point. Buddha was an active person but had great repose in himself (*acquiescentia in se ipso*). Long before he died he is said to have reached Nirvana, which, properly interpreted within Mahāyāna Buddhism, involves supreme integration and liberation of the personality, implying bliss or (in the terminology of Spinoza) *hilaritas*. Research by F.Th. Stcherbatsky (1974) and others concerning the term *dukkha* (conventionally translated as “pain”) shows that so-called pessimistic Buddhism also has a doctrine of joy as a central aspect of reaching freedom in Nirvana.

One may say, somewhat loosely, that what we now lack in our technological age is repose in oneself. The conditions of modern life prevent the full development of that self-respect and self-esteem that is required to reach a stable high degree of *acquiescentia in se ipso* (the term *alienation*, incidentally, is related to the opposite of *in se*, namely, *in alio*, wherein we repose in something else, something outside ourselves such as achievement in the eyes of others—we are “other directed”).

Humility, as defined by Spinoza, is sorrow resulting from contemplation of one’s own impotency, weakness, and helplessness. A feeling of sorrow always involves a decrease of perfection, virtue, or freedom. We can come to know adequately more potent things than ourselves. This gives us such joy because of our activeness in the very process of knowing them. The realization of our own potency, and our active relation to the more potent, results in joy. Thus, instead of humility (which is a kind of sorrow) there are three kinds of joy: first, that resulting from the contemplation of our own power, however small, which gives us *acquiescentia in se ipso*, self-respect and contentedness; second, the joy resulting from increased personal, active knowledge of things greater than we are; and third, the joy resulting from active interaction, which, strictly speaking, defines us (as well as other objects or fragments) in the total field of reality (or in Nature, in Spinoza’s terminology).

Adequate knowledge always has a joyful personal aspect because it reveals a power (never a weakness) in our personality. In Spinoza's words:

Therefore, if man, when he contemplates himself, perceives some kind of impotency in himself, it does not come from his understanding himself, but from his power of action being reduced. . . . To the extent that man knows himself with true rationality, to that extent it is assumed that he understands his essence, that is, his power.

We say with some haughtiness that Spinoza belongs to the age of rationalism, to the pre-Freudian, pre-Hitler era. Nevertheless, Spinoza in many ways anticipated Freud, and his term *ratio* must not be translated by our term *rational* or *rationality* unless we immediately add that his *ratio* was more flexible and was internally related to emotion. Rational action for him is action involving absolutely maximal perspective—that is, where things are seen as fragments of total Nature—which is, of course, not what we tend to call rational today. Spinoza was not an “intellectual” in the sense of modern Anglo-American social science.

Pity and commiseration (*misericordia* and *commiseratio*) are not virtues for Spinoza, and even less so for Gandhi, although they may have some positive instrumental value. Spinoza says that “commiseration, like shame, although it is not a virtue, is nevertheless good in so far as it shows that a desire for living honestly is present in the man who is possessed with shame, just as pain is called good in so far as it shows that the injured part has not yet putrefied.” A modest function, but nevertheless of instrumental value! Tersely, Spinoza adds that “a man who lives according to the dictates of reason strives as much as possible to prevent himself from being touched by commiseration.” People who are crippled are among those who practically unanimously agree.

Commiseration is sorrow and therefore is, in itself, an evil. According to certain conventional morality, a duty should be carried out even if there is no joy. This might suggest that we had better disregard our duties if we are not permeated with joy. This interpretation seems to me rather fanatical, however, except when one adds a kind of norm concerning the high priority of developing the *capacity* for joy. “Alas! I cannot do my duty today because it does not fill me with joy. Better to escalate my efforts to experience joy!” Spinoza does not stress the remedy to the above situation—

greater integration—but he presupposes it. The case of humility shows how *ratio* changes sorrows to joys: Spinozistic psychoanalysis tries to loosen up the mental cramps that cause unnecessary pain.

Freud worked with the tripartition of id, ego, and superego. The superego, through its main application in explaining neuroses, has a rather ugly reputation: it coerces the poor individual to try the impossible and then lets it experience shame and humility when there is no success. In Spinoza's analysis, the *ratio* also functions as a kind of overseer, but its main function is rather one of consolation. It directs our attention to what we can do rather than what we cannot, and eliminates feelings of necessary separation from others; it stresses the harmony of rational wills, and of well-understood self-interests.

A major virtue of a system like Spinoza's is the extreme consistency and tenacity with which consequences, even the most paradoxical, are drawn from intuitively reasonable principles. It meets the requirements of clarity and logic of modern natural science. The system says to us: "You do not like consequence number 101? But you admit it follows from a premise you had admitted. Then give up the premise. You do not want to give up the premise? Then you must give up the logic, the rules of inference, you used to derive the consequence. You cannot give them up? But then you have to accept the consequence, the conclusion. You don't want to? Well, I suppose you don't want clarity and integration of your views and your personality." The rationality of a total view like Spinoza's is perhaps the only form of rationality capable of breaking down the pseudorational thinking of the conservative technocracy that currently obstructs efforts to think in terms of the total biosphere and its continued blossoming in the near and more remote future.

The Philosophical Premises of Environmentalism

Personally, I favor the kind of powerful premises represented in Chinese, Indian, Islamic, and Hebrew philosophy, as well as in Western philosophy—namely, those having the so-called ultimate unity of all life as a slogan. They do not hide the fact that big fish eat small ones, but stress the profound interdependence, the functional unity, of such a biospheric magnitude that nonviolence, mutual respect, and feelings of identification are always potentially there, even between the predator and its so-

called victim. In many cultures, identification is not limited merely to other living things but also includes the mineral world, which helps us to conceive of ourselves as genuine surface fragments of our planet, fragments capable of somehow experiencing the existence of all other fragments: a microcosm of the macrocosm.

Another idea, right at the basis of a system from which environmental norms are derivable, is that of self-realization. The mature human individual, with a widened self, acknowledges a right to self-realization that is universal, and seeks a social order, or rather a biospherical order, that maximizes the potential for self-realization of all kinds of beings.

Levelheaded, tough-minded environmentalists sometimes stress that it is sheer hypocrisy to pretend that we try to protect nature for its own sake. In reality, they say, we always have the needs of human beings in view. This is false, I think. Thousands of supporters of unpolluted so-called wastelands in northern Labrador wish simply that those lands should continue to exist as they are, for their own sake. They are of intrinsic, and not only instrumental, value. To invoke *specifically* human needs to describe this situation is misleading, just as it is misleading to say that it is egotistical to share one's birthday cake with others because one *likes* to share with others.

Self-realization is not a maximal realization of the coercive powers of the ego. The "self" in the kinds of philosophy I am alluding to is something expansive, and the environmental crisis may turn out to be of immense value for the further expansion of human consciousness.

In modern education the difference between a world picture—or better, a world model—and a straightforward description of the world is slurred over. Atoms, particles, and wave functions are presented as parts or fragments of nature, even as *the* real, objective nature, as contrasted with human projections into nature—the "colorful" but subjective nature.

So-called physical reality, in terms of modern science, is perhaps only a piece of abstract mathematical reality—a reality we emphatically do not live in. Our living environment is made up of all the colorful, odor-filled, ugly or beautiful details, and it is sheer folly to look for an existing thing without color, odor, or some other homely quality. The significance of this subject is a broad cultural one: the rehabilitation of the status of the immediately experienced world, the colorful and joyful world. *Where* is joy in the world of fact? Right at the center!

Politics and the Ecological Crisis: An Introductory Note

“Everything is politics!” This was a powerful slogan in Western Europe during the 1960s, the years of student revolts. This slogan meant for the students that the emerging environmental movement had to be politicized. No real progress toward solving the ecological crisis would be made unless ecological problems were seen as questions of policy. Politicians had to be warned that they would be voted out of office if they attempted to block antipollution and other ecological legislation. With no powerful pressure groups advocating strong environmental legislation, most politicians felt that they could not risk moving from vague environmental promises to strong, concrete proposals. Although the student radicals underestimated important aspects of the classical “unpolitical” conservation movement, nevertheless they did have a beneficial influence on politically activating mere “nature lovers.”

In Eastern Europe, the international ecological movement was inevitably politicized, but in a wrong way. Political leaders in these countries interpreted it, or pretended to interpret it, as an effort to undermine centralized industrial projects, and thus as a subversive activity. Consequently, even less was accomplished by the movement than in Western Europe.

It is important to note that Rachel Carson’s political *Silent Spring* (1962), from which we date the beginnings of the international deep ecology movement, insisted that *everything*, every aspect of society, not just politics, would have to be changed. The controversy that Carson’s book

This article was reprinted with permission from *ReVision: A Journal of Consciousness and Transformation* (Washington, D.C.: Heldref Publications) 13 (Spring 1991): 142–46.

elicited brought to light the issue of the covert cooperation between the U.S. Department of Agriculture and the pesticide industry. The uproar stemming from Carson's charges against the pesticide industry made it clear not only that very powerful pressure groups would influence votes against necessary changes in the direction of responsible ecological policies, but also that those groups had the clout to monopolize the mass media with counterinformation. For example, they claimed that there was no reason to ask for significant changes because the environmentalists were exaggerating; that new technologies, various natural science projects, and a few environmental laws were all that was needed to solve environmental problems and then they could get back to business as usual.

Consequently, it was not deemed necessary to hold discussions and engage in dialogues concerning the fundamental philosophical issues surrounding the ecological crisis. It was not necessary to question the deepest premises of the way of life in the rich, consumerist nations. Understanding of Carson remained at a shallow level from the point of view of premise/conclusion relations.

Ecologically beneficial technologies, such as solar energy, were invented, but they could not be introduced on the large scale required without strong political backing, and that was unavailable. As the tremendous social and political obstacles to the needed ecological changes were exposed, unhappily only a small minority of people in a minority of countries stood firmly behind the necessity to make these changes. Unfortunately, that is the situation even today.

It is appropriate to talk of the "deep" and the "shallow" ecology movements as being characterized by marked differences in argumentation patterns. The deep ecology argumentation pattern was generally rejected by industry and most of the public as leading to a blind alley, and as being pernicious because of its alarmist and even subversive character. I refer to this as an *argumentation pattern* because the differences between the deep and the shallow movements are not always discernible if we focus only on individual arguments. For example, members of the deep ecology movement support many of the arguments made by shallow ecology proponents for certain changes, such as the move toward technologically "green" products.

Because of the multiplicity of political parties and the relative ease with which they can be formed in Western Europe, the politicization of the

ecology movement is easier to trace there than in the United States. It would be wrong to suppose, though, that supporters of the deep ecology movement in the United States have been politically passive. Their politics have generally taken the form of infiltrating and influencing the two major political parties, the Democrats and the Republicans. There also have been occasional political victories, such as the passing of laws requiring major industries to choose less ecologically sensitive areas in which to locate new factories.

Ecological Sustainability

Moving now to the more philosophically fundamental issues of ecological politics, I wish to deal with the question, What are the *means* and what are the *ends* in the political fight for responsible ecological policies? With regard to ends, I propose the following axiom: *Long-range local, district, regional, national, and global ecological sustainability is the criterion of ecologically responsible policies as a whole.* Unsustainable policies can be allowed only as necessary ad hoc evils, but that tolerance must be only temporary. When the norm of “sustainability” is used in the following discussion, it refers to the sense of encompassing sustainability as described in the above axiom.

It is now largely accepted among politicians that some sort of sustainability is a necessity. Therefore, one should be prepared for usages of the term that are both much narrower and much weaker than the one suggested here. It actually may mean very little when a government or government-dominated agency declares a policy ecologically sustainable. The same holds for the term *biodiversity*. “Maximize biodiversity!” is a very strong norm as promoted by conservation biologists, and it is derivable from our axiomatic norm of sustainability.

The goal of ecological sustainability is, however, only one of the goals of a green society. A great deal of valuable literature has been devoted to outlining the characteristics of a green society, and it is important to retain a vision of what we would consider a perfect green society. Among the proponents of the ideals of a green society, there is fairly substantial agreement that an established green society will have reached three main goals, of which only one is ecological sustainability. The other two are the goals of the peace movement and the goals of the social justice movement (if we al-

low the term *social justice* to have a broad meaning that includes the elimination of large-scale human starvation and subjugation).

It is often asked, What are the politics of the deep ecology movement? Do not deep ecology supporters have a political program? These are badly posed questions, for there is no green-party political program derivable from the views that the supporters of the deep ecology movement hold more or less in common.¹ Furthermore, the movement exists in many countries, and those countries have different traditions and various political systems.

Considering the accelerating rate of irreversible ecological destruction worldwide, I find it acceptable to continue fighting ecological unsustainability, whatever the state of affairs may be concerning the other two goals of green societies. I find this to be so despite the completely obvious requirement that there needs to be significant progress toward the goals of the peace and social justice movements in order fully to reach ecological sustainability. Because of the unique features of the ecological crisis, many political initiatives and goals relating to its solution must proceed with only minor reference to the ultimate goals of a green society. The “greening” of policies must be constantly kept in mind, but not necessarily the ultimate steps toward a perfect green society.

If there is any doubt concerning the need to act quickly on a number of ecological fronts, consider, for example, the depletion of our forests. The World Watch Institute’s proposed worldwide reforestation project (1988) estimates that it will take an expenditure of between five and ten billion dollars from the year 2000 onward to save and replace our forests. We are now even more clear in our understanding of the differences between a forest and a species-poor plantation of trees, and know that the costs of reforestation will be even higher than originally anticipated. The rich countries, of necessity, will have to bear most of the burden of these costs, if it is to be done at all.

In the early 1970s, there was substantial agreement on a number of features of green societies—for example, decentralization and the establishment of strong, fairly self-determining local communities. It is now clear, though, that in areas of the world where pollution and other environmental problems are still minimal, the people who hold influence or power tend to favor the kinds of development that people in more polluted areas increas-

ingly resist. To save what can still be saved in areas contributing only moderately to the ecological crisis, political institutions in larger, more polluted areas must pressure the smaller, less-polluted and damaged areas to adopt restrictions on ecologically damaging practices. The anger, indignation, and fierce resistance of the more local political institutions underscore the present deep-seated pressures to continue to “develop” along the lines of the most exploited areas. I put the word *develop* in quotation marks because it is development inconsistent with the requirement of ecological sustainability. The unfortunate necessity of occasional coercion can be justified in part by an application of the norm of *universalizability* (i.e., that if ecological sustainability is a necessity for any area, then it is a necessity for all areas).

Classes of Ecological Unsustainability

Let us suppose that we were able to group areas into three classes: (1) those with a level of unsustainability considerably below the average, (2) those with roughly an average level of unsustainability, and (3) those considerably above the average level of unsustainability. Let us further suppose that a political party in the first class argued that certain unecological policies could justifiably be pursued because their implementation would merely bring that area nearer the average level of unsustainability. This political party probably assumed that others in the first class would not do the same, for if they all did, it would significantly increase the average unsustainability, a situation contrary to what all classes now agree must be avoided. In this case, people in the first class are asked to follow a norm of forced status quo in terms of their degree of unsustainability, that is, a forced limitation on their self-determination in these matters. This course of action would protect those areas in the third class so that people there would not have to go through a severe period of transition toward sustainability. Thus, a thoughtless increase in unsustainability would be prevented, as well as the resulting painful change of direction. This is not a question of arbitrary coercion but rather of sanctions drawn within the limits of carefully considered legislation.

The above line of reasoning and proposed solution would, no doubt, be resisted within some “radical” environmental circles. The ghost of ecologi-

cal dictatorship is liable to be raised, as well as that of undesirable hierarchical sociopolitical structures. Therefore, it is important that as many people as possible articulate clearly the means and goals of policies that lead to a decrease of unsustainability. One may justifiably object to the above classification scheme on the grounds that some areas exist that have attained full sustainability (i.e., human and other activities do not result in a decrease in the full richness and diversity of life-forms in the areas). Such areas, though, are few and small; not even Antarctica qualifies as fully sustainable. The objection may also be raised that it is more important to apply such a classification scheme to states, countries, and other political and administrative units. If we neglected geographical areas, however, the Earth's natural subdivisions would be ignored. For example, the eruption of Mount Saint Helens decreased the richness and diversity of life-forms over a large area encompassing several political jurisdictions; it went from class 1 or 2 to class 3 in a very short time. Thus, the geographical point of view of the Earth is of some importance in devising these classification schemes. Further, the biodiversity of the Mount Saint Helens areas should be restored—in short, we wish to protect the richness and diversity of life whether or not decreases in richness and diversity are caused by human beings. Another example is the Barents Sea, which is now a large class 3 area. In this case, the “criminal” policies of several countries, together with the irresponsibility shown by certain occupational groups, have severely decreased the populations of various species of fish. It is open for discussion whether certain “natural” processes are also at fault, but the point of view taken is that, in the end, we wish the Barents Sea to recover.

At a national level, interesting conflicts along the above lines arise. If Norwegian politicians agree to increased gas production from the North Sea area, it will lead to an increase in Norwegian production of atmospheric carbon dioxide. If this happens, Norway will not be able to stay within the limits its government has promised the world it will not exceed. The government claims that the carbon dioxide production of an area larger than Norway, namely that of the European Common Market, and, of course, the world as a whole, will diminish as a result of the North Sea production. The government points out that because Norway would be exporting nearly all the gas, the importing countries would reduce their more ecologically unsound energy production from coal. If this were indeed the case, the in-

creased development of the Norwegian gas industry seems to be a step toward less unsustainability in a wider global area.

Several relevant arguments can be offered against the government's decision, however. First, long-range policy must be that of stabilization and reduction of the use of energy and, in particular, energy produced by non-renewable resources. Second, the energy used to develop Norway's gas industry and to transport the gas to foreign countries would be considerable. If such foreign countries were to indicate to Norway that they had a coal-reduction program, and were then to ask for gas to replace a certain percentage of their coal, the ecological situation would be quite different. The departments of foreign affairs must be drawn into these ecological considerations. At present, they are mainly preoccupied with commercial matters.² From the point of view of the deep ecology movement, both a trend toward centralization of political decisions and a trend toward decentralization must be envisaged. The policies of local communities, in many areas of ecological conflicts, must be controlled by regional and national political authorities. These again, to a much higher degree, must be controlled by institutes that are global (not only international) in scope. Nevertheless, many ideals of strong local communities formulated in the 1960s and 1970s can be retained.

Green Politics

The building of a green party at the national level is occurring only in the relatively few "democratic" countries. It is necessary for green politics to spread to other parts of the world. The content of the various green party programs will have to adapt to differing political and ecological situations and will inevitably show great differences. Internal strife can be kept to a minimum by being clear about the differences between the fundamentalist and the pragmatist positions in green parties. Fundamentalists take a hard stand on ecological issues; pragmatists are willing to consider compromises for social justice's sake, for example. Some compromises will have to be made. In Norway, fundamentalism has been strong, although there is a willingness to maintain the welfare profile of the political left. The following is a short résumé of the Norwegian political program as one example of green politics in a First World country.

The publication describing the Norwegian green program consists of ten chapters, the first of which outlines the "basic values." The first two sentences read: "We who are alive today have an obvious responsibility, in relation to future generations, for other life-forms and for the global community. The Greens wish to leave behind them an Earth at least as rich and diverse as the one we humans have inherited." The phrase "global community" does not mean the same thing as "human community"; rather, it refers to the coexistence of *all* living beings in the Earth's ecosphere. Richness and diversity are intended to include deep human cultural diversity as well. Clearly, it is implied that we human beings have many special obligations toward our fellows.

Twelve points are then listed that outline the Greens' basic tenets, one of which is that current rates of economic and social development can proceed only at the cost of seriously degrading the quality of life. Other tenets hold that social and global solidarity implies reversing the trend toward growing differences between rich and poor; that increase in the material standards in the rich countries must be reversed; and that bureaucracy and the power of capital must be reduced. These reversals are the inevitable consequence of emphasizing certain basic human values, not of achieving them as independent goals in themselves.

Other basic values in the Norwegian green program include a technology adapted to nature and human beings, cultural diversity, viable local communities, and a respect for nature and life. Other key issues include an increase in the minimum wage; the redistribution of wealth; decentralization and the support of small organizations; the participation of children and the old in productive work; ecological architecture that gives small children access to free nature, not just parks; transfer of military resources to environmental tasks; global cooperation and security; and the support of groups who work for alternative kinds of societies.

The above list of key issues provides an impression of the comprehensiveness of the Norwegian Green party program. Like the programs of most European green parties, the Norwegian program tries to include the main concerns of the three great social movements of our time: the peace movement, the social justice movement, and the ecology movement. This is a formidable task and requires great discipline. In my opinion, the extreme positions within the three movements cannot all be accommodated.

For example, antiracist feelings are strong in Norway, resulting in liberal immigration policies for Third World countries. Unfortunately, these feelings often overpower ecological considerations. Because today's lifestyles in the richer countries ensure gigantic waste per capita, compared to those of the poor countries, every immigrant from a poor to a rich country creates more ecological stress. It is clear that the children of immigrants will likewise adopt the fatal consumption patterns of rich countries, thereby further adding to the ecological crisis. In my estimation, green parties, including the Norwegian one, do not sufficiently see that these feelings of solidarity and compassion, especially for children, demand a tenfold increase in contributions to Third World countries to aid in their daily fight against devastating hunger and degrading torture as a more ecologically sound solution. The main driving force of the deep ecology movement, as compared with the rest of the ecological movement, is that of identification, and thereby solidarity, with all life. Human beings are our nearest, in terms of identification with all life, and green parties should include political plans for participation in the fight against world hunger and for basic human dignity. A green program in the richest countries should include a proposal to help poor countries that are invaded by immigrants from still poorer countries. It is likely that such phenomena will increase in the future. Immigration policies must be seen in a global context.

It is a widespread practice to accuse politicians, and the heads of political parties, of being weak in their support of environmental matters, of adopting green slogans but never proposing strong actions to solve the ecological crisis. To act, party politicians must have voter support, and it is fairly clear that powerful pressure groups, whose well-organized, effective action supports special interests and influences votes, will fight any decisive ecological program. Politicians will not propose programs or projects that are unacceptable to the leadership of major pressure groups. Special-interest-group democracy, as it functions today, prevents major changes in ecological policies. Therefore, people need help to recognize the inconsistencies between statements made for public consumption and political effect on the one hand and actual behavior on the other. For example, politicians may profess strong environmental concerns but, through their actions, be responsive to special-interest groups that prevent responsible ecological policies from being adopted, or even proposed, by the main po-

litical parties. What everyone can do in this situation is to spend some time analyzing how he or she, directly or indirectly, supports the continuation of local, regional, or national policies that are ecologically irresponsible.

The special role of the deep ecology movement in political life has several aspects. It rejects the monopoly of narrowly human and short-term argumentation patterns in favor of life-centered, long-term arguments. It rejects the human-in-environment metaphor in favor of a more realistic human-in-ecosystems and politics-in-ecosystems one. It generalizes most ecopolitical issues—from “resources” to “resources for . . .”; from “life quality” to “life quality for . . .”; from “consumption” to “consumption for . . .”—and in “for . . .” we insert “not only for human beings, but for other living beings.”

Supporters of the deep ecology movement have, as a main source of motivation and perseverance, a philosophical-ecological total view (an ecology) that includes beliefs concerning fundamental goals and values in life, which they apply to political argumentation. That is, they use *not only* arguments of the usual rather narrow kind, but also arguments from the level of a deep total view *and* with the ecological crisis in mind. Supporters of the deep ecology movement do not consider the ecological crisis to be the only global crisis; there are also crises of social injustice and of wars and organized violence. There are as well, of course, political problems only distantly related to ecology. Nevertheless, the supporters of the deep ecology movement have something important to contribute to the solution of these other crises: they provide an example of nonviolent activism that will be needed in the years to come.

The Politics of the Deep Ecology Movement

Some Key Slogans of the Deep Ecology Movement

By definition, what is called the deep ecology movement explicitly bases its activity on philosophical or religious premises.¹ These can differ considerably without disturbing the fairly uniform character of the aims of the movement's supporters. I shall quote some statements typical of those environmentalists who support what is now often called deep ecology.

1. "Earth First!" This is a slogan expressing the opinion that the maintenance of the richness and diversity of life on our planet must be considered a first-priority goal. It supersedes the goal of a maximum number of people with a maximum standard of living. It supersedes any other goals but implies the maintenance of a population of human beings sufficient for cultural diversity and a high quality of life. This is accepted because it is necessary for realization of the maintenance goal for the Earth itself.
2. "Why more than 100 million human beings on Earth?" This rather rhetorical question is posed to familiarize people with the conception that the present-day size of the human population has a tremendously negative impact on conditions for life on the planet and that a long-term plan for substantial reduction would not threaten life quality. Of course, the plan would have to be consistent

This article was reprinted with permission from *Wisdom in the Open Air: The Norwegian Roots of Deep Ecology*, edited by Peter Reed and David Rothenberg (Minneapolis: University of Minnesota Press, 1993), 82–99.

with the basic rights of the human *as a living being* and never resort to crude coercion.

3. "An injury to where I belong is an injury to me!" This slogan reminds us that the human self is a part of many gestalts. The skin is not our limit. Therefore, the term *environment* is not popular among some supporters of deep ecology, because an environment may imply the separation of an organism from its surroundings and, as such, does not foster feelings of participation, identification, or expanded notions of the self.
4. "Animals, plants, and landscapes have intrinsic or inherent value independent of narrow human usefulness." This slogan is used to undermine our tendency to rely only on short-term, opportunistic economic and health arguments when supporting the fight against pollution, resource depletion, the extermination of species, the destruction of ecosystems, and other calamities for long-run survival and well-being. The slogan is intended to make us fight also for the planet and its phenomenal qualities.
5. "Simple in means, rich in ends!" Human interference in the eco-sphere can be reduced to tolerable levels only if people, and especially those of us in the industrial states, adopt lifestyles requiring simpler material means. This is compatible with, or even favorable toward, richness of goals.
6. "Increase the sensitivity to and appreciation of what there is enough of for all!" This instructive slogan fights against the confusion of real value with market price: a way to maximize our ability to derive deep satisfaction from the goods of which there still are, or could be, enough. The current lifestyle of people in the industrial societies cannot become a global lifestyle without irreversible and colossal destruction of the conditions of life on Earth.
7. "Mother Earth has no use for modern war!" Modern armaments and wars are ecological catastrophes. The peace movement is not just a movement on behalf of human beings. Deep ecology embraces movements for disarmament and for nonviolent solutions of conflicts.

Philosophers of the deep ecology movement may be said to be people who never found biological, political, or other arguments that undermined those attitudes implicit in childhood, whereas those in the shallow envi-

ronmental movement seem to have fallen sway to the times, letting narrow human interests dominate: other life-forms are seen as beings only to be used, enjoyed, and managed by human beings. From these hints about what supporters of deep ecology think and feel, I shall move on to discuss some political aspects of the movement.

The Three Poles of the Political Triangle and the Limitations of Triangular Analysis

Ecopolitics is a widely used term in northern Europe. Sometimes it is used synonymously with what I would call “good or responsible ecopolitics.” I prefer to use it, like *ecophilosophy*, as a fairly neutral term for “politics with reference to ecology” or “political aspects of ecological problems.” Instead of “good or responsible ecopolitics” I use the term *green politics*. There are five general points about green politics that I would like to mention here:

1. One convenient way of naming the main contemporary currents and parties in industrial countries is to present a political *triangle*, with each point representing one of three main political poles (figure 3). The colors used to label the poles are familiar symbols in European discussion.

Figure 3. The Political Triangle

It is essential for supporters of green policies to maintain and show that they cannot be placed on the line between red and blue. A second dimension is needed. Roughly 10 percent of Swedish and Norwegian voters feel at home around the green pole. It is also essential to keep in mind that political abstractions such as green, red, and blue are dangerous if taken as being merely points. They are more like *magnetic* poles: dynamic pulls in more or

less singular directions. They must be distinguished, then, from particular parties or platforms themselves, which are definable in relation to the poles.

So we can try circles (figure 4). If circles are used, they are overlapping. Most supporters of green politics see a greater affinity between green and red than between green and blue, but from a broad historic and systematic point of view it is prudent to let the circles overlap equally, rejecting any quantitative interpretation of the overlapping areas.

Examples of similarity between green and blue include stressing the

Figure 4. The Political Circles

value of personal enterprise (overlapping the blue private enterprise) and a very high priority of fighting bureaucracy. Similarities between green and red include stressing social responsibility and a very high priority of fighting undesirable ethical, social, and cultural consequences of the unrestrained market economy.

Political parties can roughly be located within or along the borders of the political triangle, but more accurately (although still in a rough way, of course) in three dimensions, using an ordinary Cartesian coordinate system (figure 5). Here each “element” (blue, green, and red) is not linearly independent. The essential point, though, is that green is *not merely another point, circle, or dimension*. It is a dynamic wavelike force, an intuition or sudden realization that should affect all points along any shallowly conceived spectrum or frontier of political opinions. Hence the British Ecology Party

makes it clear that its own existence will be rendered unnecessary by its success, as “all parties will in time become more or less ecological” (Porritt 1984: 36).² A quite ecological attitude about one’s own existence!

Figure 5. Cartesian Coordinate System

So, probably the most satisfactory diagram would be one that indicates clearly the more dynamic nature of the green influence upon the other two. We may see it as an axis, which pulls the others toward it as asymptotes (figure 6).

Figure 6. The Political Axis

2. Every political decision has green relevance; as a consequence, green parties must be big enough to have people well versed in each of the major issues. (No single politician can really be well informed on all.) It is not enough to take up the problems that people in general perceive as being typically ecological (nuclear energy, acid rain, etc.).

3. In industrial democracies, the supporters of green policies must keep track of how the politicians of the various parties talk *and vote* on specific matters, evaluating them from the green outlook. Their ecology "score" should be widely publicized. The same holds for party platforms, although experience, at least in Scandinavia, suggests that every party platform can look as if responsible ecological policy is being taken seriously, whereas decisions may turn out to be consistently ungreen.

4. A major part of political debate today is economic. To take part in it, supporters of green politics should try to acquire a clear conception of the main factors of their country's economic system and try to articulate how the system differs from a green economics.

One of the characteristics of green economics is the insistence on distinguishing need from demand on the market. The so-called need for more parking space is a demand that may or may not express a need. There is a need to work not far from home, but public transport may largely decrease the demand for parking space. Demand for luxury foods in a starvation area is practically zero—there is no money available and no market. The maximum demand for foodstuffs is in the richest areas of the world—to feed animals or to fuel industry—but where is the need greatest?

5. People have reason to entertain suspicions about societies planning to implement green policies: do they not ask for still more regulations (laws, coercive rules, etc.) than we already have? The tame answer is "Not necessarily!" To avoid such a tendency, organizers must constantly strive to keep down regulations. A typically blue attitude? Yes and no: private industry is, in spite of its official "free and competitive" nature, shot through with regulations, mostly unknown to the general public but no less coercive for that. The smaller-unit industry of green societies will, because of a less hierarchical power structure, among other reasons, need less regulation. Much depends on change of mentality: the less change in the green direction, the more regulations there will be.

If-Statements and Exponential Growth

Politicians suggesting the wisdom of radical green programs have sometimes been discredited as doomsday prophets. Through the mass media the public was, in the late 1960s and early 1970s, told that there were ecologists predicting catastrophe very soon. As nothing seemed to happen that fulfilled these prophecies, the public was placated.

No well-known ecologist has *predicted* a human-caused ecological catastrophe. By the term *ecologist* I here refer only to trained active researchers in ecology, and I limit my contention to published predictions. (What some ecologists may utter in private I do not pretend to know.) Therefore, it is not today a high priority to discuss political moves under immediate threat of ecocatastrophe. On the other hand, many well-known ecologists have predicted that *if* certain trends continue, destruction of gigantic dimensions will take place on our planet within a hundred years or less.

An example of such if-statements: “*If* the present growth trends in world population, industrialization, pollution, food production, and resource depletion continue unchanged, *then* the limits to growth on this planet will be reached sometime within the next one hundred years.”

Other statements are of a much graver kind, *but are still if-statements* and still with comments implying that we have not reached a point of no return. An example: “Humanity will ultimately destroy itself if we thoughtlessly eliminate the organisms that constitute essential links in the complex and delicate web of life of which we are part.”

Such statements are meant as warnings, and the authors most likely hope that action will be taken to change politics deeply so that the warnings will not be realized as truths. Also politically significant are the predictions that the longer we wait before we start making radical changes, the more terrifying will be the necessary political and other means to reestablish planetary richness and diversity of life, including a decent human quality of life.

The doomsday terminology is the invention of *opponents* of the deep ecology movement. The same holds true for expressions like “zero growth.” This is borrowed from demography and is rarely used by supporters of deep ecology today. They criticize the GNP calculations as basically misleading as they are used in blue economics, and still more as they are used in blue

politics. Green politics cannot have as part of its program the increase of GNP, which perhaps should be read as "gross national pollution." Moreover, there is no new measurable quantity, say "gross national life quality," that could take over the role of GNP. The whole way of thinking that places such weight on a single statistic is in question.

The frantic efforts to maintain economic growth in terms of GNP mean that, on the whole, damaging interventions in ecosystems increase exponentially rather than arithmetically. When a forest is reduced in an arithmetic way, life conditions tend to worsen in an exponential way when the area approaches zero. The difference between exponential and arithmetic growth cannot be overemphasized. If you place pages of paper on top of one another, and each page is one millimeter thick, you would need a thousand pages to reach the thickness of a single meter. If, however, you fold a single piece of paper over and over again, then the thickness grows exponentially as the series 1, 2, 4, 8, 16 . . . , which means that you reach the thickness of a meter (or more accurately, 1,024 millimeters) after only ten foldings, and a thickness of 1,048,576 millimeters, that is, a thin column of paper 1,048 kilometers high, after folding it only twenty times. The public needs to fully understand the *exponential character* of growth measured in percentages.

The decrease of life quality in general is a theme that has been largely neglected in political discussions. Attention has been concentrated on immediate health problems for human beings, the economic loss through death of fish in hundreds of thousands of lakes, and, very recently, the economic loss through dying forests. The shallow approach asks for acid-resistant fish and trees, or questions the economic importance of fishing and forestry when compared with industry, or goes so far as to say, Why even have forests in West Germany if they are not compatible with the country's industrial growth? The contribution of these forests to life quality is being neglected.

Checklist of Ecopolitical Issues

Question: What is the proposed politics of x in regard to subject y ?

x = a person, an institution, a nation, a group

y = any of the subjects listed below

- I.A. Politics of pollution of human environment
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. class aspect: local versus regional versus national versus global perspective
- I.B. Politics of pollution of the habitat of other life-forms
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. discrimination: favored versus unfavored life-forms
 - 4. politics related to specific species, ecosystems, landscapes
- II.A. Politics of resources for human beings
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. class aspect: local versus regional versus national versus global perspective
- II.B. Politics of resources for nonhuman life-forms
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. discrimination: favored versus unfavored life-forms
 - 4. politics related to specific species, ecosystems, landscapes
- III.A. Politics of population of human beings
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. class aspect: local versus regional versus national versus global perspective
- III.B. Politics of population of nonhuman beings
 - 1. short versus long time perspective
 - 2. local versus regional versus national versus global perspective
 - 3. discrimination: favored versus unfavored life-forms
 - 4. politics related to specific species, ecosystems, landscapes

These three classes of issues constitute the core of ecopolitical issues in a narrow, standard sense. The above list may be helpful, but there is a wider, and in my terminology, deeper sense in which ecopolitical issues also cover many problems within traditional politics. In relation to I.A–III.B, green politics opposes the red, and especially the blue, in the following ways:

1. We have a long time perspective. We intimately feel that we are parts of an emanation of life wherein a million years is a short time. We are concerned with soils that can be destroyed in five minutes but that would take a thousand years to restore. We are unimpressed by short political election periods and reject the superstition that a few years of research and technical development can solve any major ecological problems of any kind. Nevertheless, we must be alert and try to anticipate the next moves of our governments and their primary unecological agencies (e.g., the so-called forest services; the Environmental Protection Agency in the United States).

2. Green politics combines local and global perspectives, trying to tone down the excessive role of national and international structures. What is known as "national identity" should be based on local communities. Inter-local communication largely supplants international. So-called assistance to the Third World (e.g., by the organization The Future in Our Hands) is done through direct contact between local communities. It is difficult to avoid governmental institutions, but nearly a thousand global nongovernmental institutions are headquartered in Geneva and can be used to facilitate interlocal rather than international contact.

Education will largely concern the local and the global. Green schools are available in many places today, but there are thousands of graduates who cannot find work along their preferred lines. The public and the bureaucracy should come to realize the great value of the interdisciplinary education provided by such schools, and thus welcome their graduates heartily into many kinds of respectable employment positions.

The main arguments used in Norway when rejecting membership in the European Common Market (EEC) in 1972 were mainline ecopolitical arguments (issues I.A and III.B). We rejected centralism endangering local and "peripheral" populations, forced worker mobility, increased competitiveness in the world market. We said no to the introduction of four times as many officially accepted medicines, and we said no to opening still wider our gates for immense European and multinational firms.

3. Green politics supports the elimination of class differences locally, regionally, nationally, and globally. The global aspect makes it clear that practically everyone in the rich industrial states belongs to the global upper class. This is easily forgotten by trade unions and by some Marxist-Leninists who still unilaterally focus on the liberation of the workers of their own country.

The core of class suppression may be seen basically as a cross-generational

suppression of life-fulfillment potentials in relation to fellow beings, or in my terminology, possibilities for Self-realization.

The politically significant *green-red alliances* in Scandinavia use this name because green political issues are mostly conceived rather narrowly as comprising only issues I.A through III.B. If we adopt such a narrow concept, a great many political problems seem to fall outside the green framework. However, all political issues can be considered from a green perspective.

To finance ecologically important projects, supporters are dependent on private and public funding. This means that one usually has to give priority to projects that people with power or people with money think should have priority, and then hope that some of the money and equipment can be quietly put to work on projects that should have priority according to deep ecology. In short, politically accepted tactics must be taken seriously, however distasteful this may seem. Talk more about cancer, and dollar bills may come flying through your open window! The same is true for the fight against *easily seen* effects of pollution. Acid rain is now taken seriously in West Germany because an important pressure group, the owners of forests, discovered that they could *calculate* losses in terms of money, and because more and more people could *see trees dying* all around them.

The political function of science deserves to be mentioned. The belief is widespread that because some scientists now work for governments, politics has become more scientific than in the days of Louis XIV. There is little evidence to support this. In ecopolitics three main factors operate against scientific influence. First, politicians ask ecologically relevant questions that scientists find impossible to answer except perhaps after long periods of large-scale research. So politicians conclude, Science has *not* found it dangerous or detrimental to do such and such; therefore, why not do it? Or, as in Britain today, the government says that the theory of acid-rain destructiveness has not been scientifically *proved*, so let us postpone costly methods of control for at least five years.

Second, the cautious language of some scientists (or philosophers) may always be used to postpone. Third, the government knows that scientists do not always agree with one another. One or more scientists can always be found who do not publicly condemn unecological policies, and these are then given power. For reasons already mentioned, saving spectacular animals receives better financing than saving more modest creatures that are more important for their ecosystems. Giant pandas and California condors

are showpieces. It is estimated that recovery efforts to help the condor will cost \$25 million over the next forty years. Tactically, propaganda in favor of the spectacular may pay off, but tactics may go too far.

The recent effort in Australia to save toads crossing highways on their way to breeding sites by use of road signs shows the way to a more “democratic” and “egalitarian” ecopolitics. Philosophically, the trend is remarkable.

Malthusianism

It is of crucial importance for the political left’s efforts to limit human populations to eliminate certain misconceptions about Malthusianism. Malthusian theory has two parts, one of which is acceptable and important from a green point of view, and one of which is completely unacceptable.

The first part concerns food increases versus population increases. Let us say that there are one million people in a territory, and let us suppose that they get food by cultivating one square kilometer—using fantastically “advanced” technology. Let us further assume that the population doubles very slowly, say every hundred years. Even then, it is clear that the geometric (exponential) ratio of increase makes our planet overcrowded after only a small number of centuries. The number of square kilometers on Earth is finite! Malthus makes this important point by considering the likely effects of “unchecked” population growth. Today, human population is largely unchecked, and it would be a Herculean task to check it.

From theoretical demography Malthus jumps to social philosophy and politics. To understand Marx’s hatred of Malthusianism, one must read Malthus’s most extreme views: everyone must delay the establishment of his own happiness until, through his labor and savings, he has put himself in a situation in which he can provide for the needs of his family. The man responsible for disobeying this injunction should rightly be punished, even if this causes his wife and children extreme suffering.

To the punishment therefore of nature he should be left, the punishment of want. He has erred in the face of a most clear precise warning, and can have no just reason to complain of any person but himself when he feels the consequences of his error. All parish assistance should be denied him; and he should be left to the uncertain support of private charity.

(Malthus 1872)

What also infuriated Marx was Malthus's talk about laws of nature and laws of God. Nothing could possibly eliminate poverty; misery was a scientific necessity!

The hatred of Malthusianism is worth mentioning because it may have indirectly led political parties on the left everywhere to shun any talk of human population control by political means. To rationalize this negligence, which is so dangerous from a green point of view, the most improbable views about salvation through industrialization have been current in the Third World since the 1920s. In India, for example, it has until recently been common to point to the population density of England or Holland: population control was said to be unnecessary because "industrialization in these European countries shows that Malthus is wrong! The greater the population, the higher the standard of living for all!"

In Scandinavia and perhaps in all the rich industrial countries, it would today be politically suicidal to propose plans for population reduction. From a green point of view there are, however, only two options: either a complete restructuring of economy and technology, or population reduction. It is to be deplored that groups near the red pole in politics tend to neglect (human) population problems and that those near the blue pole forget that one more baby in the overdeveloped countries is a much graver ecological threat than one hundred more in the slums of Calcutta.

A person active in politics should try to make it clear to the public that he or she as a private person may entertain some views that are completely unrealistic in terms of accomplishments within election terms but that nevertheless are important for his or her personal political motivation. The impact of continued population growth on conditions of life and on the ecosphere in general is intolerable and is still increasing geometrically. Even if it is *politically* suicidal to plan changes of this dimension as part of a political platform, it is irresponsible on the part of the politically active not to admit that they as private persons entertain these green views. If these views are hidden, the many people who do not play an active part in politics, but entertain radical green views, feel even more powerless than they are. They get the feeling that taking part in the struggle for power is incompatible with having green views.

The Rights of Living Beings

“Human rights” terminology has had a significant impact on politics that has been largely beneficial. Since 1945 minority groups in many countries have fought against discrimination and cruelty using rights terminology. As long as this has political impact, it is advisable not to give up the expression “*animal* rights.” The confusion about the term *rights* in philosophical and legal-academic milieus does not constitute a decisive counterargument. At least in some countries, the talk of rights of animals does not confuse people and is endorsed by the majority.

In a vast number of texts, the substitution of “human and animal rights” or “ecosystemic rights” for just “human rights” improves the text significantly from the point of view of green politics. As an example, consider such a substitution in the last part of the following quotation: “In this work, it is proposed to use *overpopulation* to refer to population sizes that exceed a country’s or the world’s capacity to provide adequately for the enjoyment of the basic human rights of all who are born into that country or the world” (McCloskey 1983: 19). In discussions, this means that questions such as the following are often relevant: You mean *exclusively* human rights? Why do you refer only to *human* rights? What about the rights of nonliving beings? The question is to some extent spurious if one adopts an expanded notion of the term *life*, including the physical life of an ecosystem, the interaction of ecosystems, and the inherent life of the Earth as a whole. The highly successful slogan “Let the river live!” attests to the power of broad ideas of living that can cover landscapes, including mountains, lakes, and oceans.

In some contexts, though, the use of the term *rights* may be confusing. If so, it may be appropriate to eliminate it in reference both to animals and to human beings.

The Deep Ecology Movement, the Peace Movement, and Their Campaigns

Fifteen years ago close cooperation between supporters of deep ecology and activists in the peace movement was out of reach. Rather suddenly, this situation has totally changed. Nuclear war would be an ecological catastro-

phe, and no life-forms except one are vitally interested in different political ideologies or big-power rivalries. Even the present level of armaments with its exponential growth is a heavy burden ecologically. One factor often overlooked is the mishandling, even torture of millions of animals in experiments involving nuclear radiation. These animals are living through a nuclear war today. (This reasoning may sound ridiculous at present in the face of the other horrors of the modern world, but in ten years such thinking should be commonplace.)

Some of us, myself included, favor unilateral disarmament and establishment of unheroic nonviolent defense. Today it is politically unrealistic in northern NATO nations to work toward getting out of NATO. This is not necessary, however. The basic documents of NATO establish it as a defense organization with no clauses against nonviolent defense. So, by promoting that sort of defense, we could be *pushed out* of NATO. A more politically realistic approach is a gradual introduction of antinuclear and nonviolent proposals from within NATO.

At this point it is important for activists to stress the distinction among action, campaign, and movement. The first comprises the direct *actions* within a campaign, for example, a demonstration at a particular place and time against the building of a dam, or the nonviolent obstruction of the transport of machinery on the way to the dam site. This may be part of a ten-year-old *campaign* to save a river (including, of course, its watershed) from development of some sort. Ten direct actions may be failures, but nevertheless their impact may contribute to the victory of the campaign. (Or may polarize the conflict, contributing to the failure of the campaign? That is what many antiactivists claim.) The river campaign together with other analogous campaigns may be seen as part of a *movement* of greater or lesser generality: a movement to save rivers or, more generally, a conservation movement. Many campaigns may be failures, but the movement goes on.

Politically, it has been important to clarify that the highly successful antinuclear campaign (as part of the peace movement) is after all only a definite, limited campaign. Supporters of a more radical disarmament, or of nonnuclear politics of various kinds, should not try to force the campaign to widen or change its identity. One may take part in several campaigns, but the frequent attempts to change the antinuclear campaign to cover

other goals are politically dangerous, leading to ruinous struggles among campaigners.

Deep Ecology and the Big Political Issues

Which political traditions or systems are most likely to color green politics? Here I am using the customary vague and ambiguous terms, and let me immediately admit that I feel uncomfortable when having to use those terms.

1. Reform or revolution? I envisage a change of revolutionary depth and size by means of many small steps in a radically new direction. Does this essentially place me among the political reformists? Scarcely. *The direction is revolutionary, the steps are reformatory.*

Of course, what I as an individual think has not much weight, and I can only say that I do not feel at home with the thought that something resembling the revolutions we read about in history textbooks, or that we may wish would take place in South America, would be of help in the industrial countries.

2. Capitalism or socialism? Although there may be said to be economic policies conveniently called capitalistic, there is hardly any capitalistic political doctrine. Socialism has such a doctrine, but is it sufficiently concerned with nature rather than its own bureaucracy?

3. Relation to communism and anarchism? Roughly speaking, supporters of the deep ecology movement seem to move more in the direction of nonviolent anarchism than toward communism. Contemporary non-violent anarchists are clearly close to the green direction of the political triangle, but with the enormous and exponentially increasing human population pressure, and war or warlike conditions in many places, it seems inevitable to maintain some *fairly* strong central political institutions. Recommendations such as those contained in the World Conservation Strategy are steps in the right direction, but there are no authorities strong enough to implement them.

Experience suggests that the higher the level of local self-determination, the stronger the central authority must be in order to override local sabotage of fundamental green policies. Or is this too pessimistic? Anyhow, the green utopias, such as those of Sigmund Kvaløy, Johan Galtung, The Future in Our

Hands, Blueprint for Survival, much like the *panchayat* utopia of Gandhi, rarely provide for significant variation in occupation and social structure in general, nor do they seriously consider the need for centralized power as long as human mentality remains similar to what it is now. Local initiatives must be encouraged! There is a great difference between units of administration and self-motivated small groups of people.

Green Political Programs from Day to Day

My conclusion here is to remind us that we need not agree upon any definite utopia, but we do need to thrash out limited programs of political priorities within the framework of current political conflicts. Our questions are of the form “What would be a *greener* line in politics at the moment within issue *x* and how could it be realized?” rather than of the form “What would be the deep green line of politics within issue *x*?” *Green is dynamic and comparative, never absolute or idealistic.*

The term *political voluntarism* may be helpful in this connection—as something to be wary of. It is a term characterizing political activity in which you think that you can rapidly force a deep change of society by sheer willpower through direct action. It was used, for example, in Marxist criticisms of students engaged in the so-called student revolutions of the late 1960s. Some Marxists said that universities are peripheral institutions: “Power inside universities does not count.” The *will* to change society by means of student power is nonsensical. You must have a much broader and more realistic basis of activity. In this sense, political voluntarism is a kind of romantic delusion.

Returning to the problem of combining basic ideals of ecopolitics and day-to-day political fights for very, very limited green gains, let us consider an example that may make the complicated situation clearer.

An energy problem exists in Norway and Sweden, but it is primarily the problem of how to reduce the fantastic *waste* of energy. It is essentially a problem of how to limit the use of energy to vital needs. From the green point of view, the current level of yearly consumption is more than sufficient for any needs. Nevertheless, some supporters of green policies take part, and should take part, in discussions concerning which sources of increased energy supply have the least detrimental consequences socially and

for life conditions in general. The situation is rather awkward: the greens are led to promote decisions they detest. As long as we constantly make clear that any increase of energy production is unnecessary and detrimental, the participation in how to increase it is justified and important. At the moment, policies of stabilization or decrease of energy production should be vigorously propagated, but politically they are dead or hibernating. Or proposals for such policies have no chance of being adopted at the moment. Today, politically powerful plans call for exponential increase of energy production until 2020. So if all available alternatives are bad, this should be said, and the worst consequences should be fought strongly.

“Everything hangs together.” This is still a good slogan. One consequence of the interrelatedness is that we all have the capacity to do something of relevance within a framework of our own interests and inclinations. The ecopolitical frontier is immensely long, but we can only work effectively at one place at a time. It is more than long: it is multidimensional, and the pull of the pole of greenness can be felt in all our political positions and actions.

The Three Great Movements

At the end of this century we see a convergence of three areas of self-destructiveness: the self-destructiveness of war, the self-destructiveness of exploitation and suppression among human beings, and the self-destructiveness of suppression of nonhuman beings and of degradation of life conditions in general. The movement to eradicate wars has a long history as a global movement. The movement against abject poverty and cruel exploitation and domination is younger. The third is quite young. These are the great movements that require intense participation on the grassroots level for the rest of this century and far into the next.

The supporters of the peace movement have always asked for policies that often have been clearly “politically impossible” for governments to accept. The same applies to the second and third movements, but today the first two can at least point to people in power who declare strong sympathy for their radical points of view. A prominent supporter of stronger NATO forces (Halvard Lange) declared that at heart he was a pacifist (which irreverently made his wife whisper, “Then I am a virgin”). Such sincere, *publicly declared* sympathy is probably not yet at the governmental level, say, in support of the deep ecology movement.

The urgency of preserving nature for “the future generations” — meaning future generations of human beings, not future generations of living

This article was reprinted with permission of Arne Naess from *Deep Ecology and Politics* (Centre for Development and Environment: University of Oslo, 1993). It is a revision of three articles, “The three great movements,” “Comments on the planned official Norwegian presentation in Rio, April 1992,” and “Politics and the ecological crisis: An introductory note.” A revised version of the article appeared in *The Trumpeter: Journal of Ecosophy* 9 (Spring 1992).

beings—has won acclaim among power elites. What I, perhaps misleadingly, have called the shallow, reform, or nondeep ecology movement has started to have an impact on the governmental level. Environmental organizations are listened to and their advice has occasionally been used in practice. However, future generations of nonhuman beings seem to be valued, at least publicly, only for the sake of future human beings.

It is the task of dictionary editors to offer definitions of the deep ecology movement. I have difficulties in doing more than proposing a tentative formulation of the views that most supporters of the movement hold in common on a fairly general level. These are the so-called Eight Points, which I shall not repeat here.

The realization of the points requires significant changes in both the rich and the poor countries and affects social, economic, technical, and lifestyle factors. The goals *include* the protection of the planet and its richness and diversity of life *for its own sake*.¹ The specific kind of urgency accorded to this third movement owes to the time factor: it is obvious that delays rapidly make the ecological crisis more difficult to overcome. Wait five years and the process may take fifty years more. Such a nonlinear function of time we do not find with regard to the other two movements.

What can be more urgent than the elimination of extreme poverty and suppression? We may answer that nothing can be more urgent, but whereas the general costs are roughly constant year after year, or increase linearly, the specific character of the ecological crisis makes the cost to reach ecological sustainability increase exponentially.

Whether in a civil war or an international war, the mentality created is that of more or less complete indifference toward destruction of nature. Destruction is even used as a weapon. To ask for mercy toward nonhuman beings would here tend to be considered frivolous. The same holds when questioning the destructiveness of the gigantic military-industrial complex that is now increasingly under ecological scrutiny, as its impact is made known in wider circles.

It is evident that the goals of the deep ecology movement cannot be reached without decisive victories of the peace movement. This should add to the motivation of people using much of their time and energy within the peace movement. Some peace people have changed focus and are now active in the ecology movement, finding the change comparable to a

change of focus within a wider peace movement: work for peace with nature, for ending brutal invasions. The change of focus undertaken by prominent peace activists such as E. F. Schumacher has not resulted in noticeable polemics about the relative importance of the two movements.

The many branches of the social justice movement have a more complex relation to the deep ecology movement.

In the West, beginning with the Industrial Revolution and continuing at least into this century, labor has been treated worse than cattle. For several hundred years pollution at the workplace and in urban slums has injured the health of the underprivileged, not the privileged.

"You speak of environmental degradation. We have suffered that for hundreds of years. You close down a factory because of poisons, but what are the consequences for you and what for us? The managers lose their jobs, but they take a long vacation in superb nature, and get new jobs. We increase the legions of the unemployed, we cannot move around easily with our family, we remain in an unhealthy environment, many lose their way of life (loggers), and our problems persist."

"You say the deep ecology movement asks for widening care so that nonhuman beings get a better chance, but you should also support increased care for the underprivileged human beings."

It is quite right that deep ecology theorists, like the peace- and social justice—theorists and activists, speak publicly about the concerns they have focused on. Their writing, if they write, also reflects their specialties. It is, however, difficult to assess what they do privately without knowing them well. General conclusions about the various concerns of the supporters of the three movements are rather shaky.

It is an embarrassing scandal that the rich industrial nations do not use the urgency of work to be done to overcome the global ecological crisis as a basis for significant reduction of unemployment. The jobs in this area are clearly more labor-intensive than jobs in industry.

Looking at philosophical "schools" of the 1960s and later, one sees clearly that anarchists, Marxists, neo-Marxists, the Frankfurt School, and hermeneutics have not felt at home with the tenets of the deep ecology movement—and not just because of the special terminology of its theoreticians. This is not the place to go into professional philosophical debates, but in spite of different philosophical and terminological leanings, three

groups—supporters of the social ecology movement, the ecofeminists, and the deep ecology movement—have cooperated well in praxis, learning from each other's special activities. The frontier of work is long, and we need to express our appreciation for work done in sectors other than our own. The convergence of problems within the three great movements may be expected to increase and their impact on policies correspondingly strengthen.

It is of historical interest to trace the various kinds of physical, social, and other changes triggering the convergence of the three movements. Here I shall not try anything like that but will merely offer some general reflections about these movements, starting with conceptual considerations.

It is not by chance that I have used the term *self* in the short characterizations of the lines of thinking, feeling, and acting. The terminology suggested itself when I was trying out a conceptual unification of a normative system with "Self-realization!" as the basic norm—expressed, inadequately of course, through a single word. For those who habitually look at the three global movements with the conceptualizations of the third movement in mind, the concept of "ecosystems," not "man/environment," is central. The human self is then basically an ecological self, that is, a kind of part of ecosystems, and the doings of human beings in war and peace and as masters or slaves are processes going on with accelerating speed and causal weight all over the globe. The self-destructiveness of current policies seems clear to a great many, and it has been adequately formulated, but to "turn the tide" seems politically overwhelmingly difficult. The self-destructiveness of wars has been announced clearly since the atomic bomb changed "everything." The long-range self-destructiveness of large-scale exploitation and suppression based on race or sex or dominant economy is by now gradually being seen to undermine the exploiters or suppressers themselves. (The false masculinity has crippled the male sex.) At least this is clear if we take into account concepts of self on a scale nearer to the great Self than to the concepts of hard egos. The development of human maturity may perhaps be said to be impaired when stiffened into counterintuitive perceptions of classes among other human beings with whom one interacts. In this case, according to my terminology, there is a limit of Self-realization not being transcended. It seems, though, that most human beings most of the time have been either exploited or suppressed most of their lives. The high levels of

self-realization have been difficult, but not impossible, to reach under such circumstances.

In most cultures some animals have been taken better care of and treated more respectfully than some human beings. During the early days of the Industrial Revolution in England, this presumably was the case with pets and even pigs. In the same country, however, a brand of utilitarianism arose that strengthened the third line of thinking and feeling—that of Jeremy Bentham (1748–1832): “The question is not, can they reason? Nor, can they talk? But, can they suffer?”

So far as I can understand, all-round maturity of human beings facilitates acts of identification with every kind of living being. This again facilitates negative attitudes toward wanton limitation of the fulfillment of life potentialities of such beings. When manifest exploitation and suppression are encountered, a reason is demanded: are they necessary for the satisfaction of vital needs of human beings? The deepening and widening of the human ecological self result in increasingly limiting its own realization when exploitation and suppression are applied. Potentialities of self-realization are destroyed. In this sense, the third movement seeks to reduce the self-destructiveness of present-day globally relevant human behavior.

Within the three great movements there are a number of organizations. One kind of problem they all have is that of eager members who wish to change or, more often, to expand the basic mandates of the organization. The successful movement against nuclear weapons in some countries had to spend much time restraining members who wished to expand into a more general peace organization. That would have reduced its thrust.

Amnesty International is a tremendously successful organization within the human rights movement—part of the general, loosely connected social justice movement (in my terminology). Its success owes in part to its careful limitation to a core problem: to get political prisoners out of more or less devastating prisons through nonviolent action. Its main procedure: letters to people in power. Because of its success, some eager members (and also outsiders) are, of course, pressing the organization to extend its mandate—for example, into being a general human rights organization.

The deep ecology movement has as a general aim to participate in overcoming the ecological crisis, but supporters have in common, for example, a strong sense of the intrinsic value of every living being and the right of

each to live and blossom that is independent of usefulness. Like other movements, especially as long as it seems to be successful, it will always be under pressure to extend its mandate. Mostly, such efforts tend to confuse rather than strengthen a movement, but cooperation with other movements is obviously an important task. The contemporary complex social situation makes isolation rather unnatural.

Again, the very special situation today must be kept in mind: an increasing portion of the populace in the industrial countries are aware of the colossal changes taking place on land, in the oceans, and in the atmosphere, changes that threaten everybody everywhere. The interconnectedness of everything is manifested in a more dramatic and convincing way than in 1970 or 1980. Many of those who were young in 1970 and got some ecological education are now firmly established and influential. It is not my job, though, to trace the ecological, social, and political factors determining the historically important convergence of the three movements and the ascendancy of the ecological issues on par with the traditionally most crucial social and political ones.

Postscriptum, 1993

I still smile, thinking about the fate of a certain criminal called Yellow Cheese (*Gulosten*) among his fellow burglars. He was also a great patriot, and the very day the Nazis invaded Oslo (April 9, 1940), the capital of Norway, Yellow Cheese ran round collecting dynamite: his personal plan was immediately to bomb the places where the Nazis congregated in Oslo. Fortunately for him and for the five-year-long resistance movement, a wiser fighter stopped him: Direct actions must be carefully planned, priorities established. Risk your life, yes, but people are needed who are not sent to German concentration camps within a week of drastic activity. Think in terms of years! Yellow Cheese understood and survived five years of fighting. Honored with a meeting with the King, he developed into a personal friend of His Majesty.

"The key is thinking BIG, both in space and in time," says Michael Soulé (1992/93: 7). Properly explained, this is not the same thing as being "moderate." Yellow Cheese was never moderate, but his later direct actions

were carefully planned and were rarely dramatic. Tactical and strategic considerations went hand in hand.

In the ecological movement there is a need to think in terms not only of days and years, but *also* of generations.

A response to the article by Soulé says a lot of things compatible with his appropriate time-scale principle: “any remaining old growth forest . . . should be afforded the highest levels of protection”; it is “unconscionable to suggest that it is not important to preserve the remaining patches on the national forests.” From a point of view of appropriate time scale, a slogan like “Stop logging old growth immediately!” is justifiable, but we know that we have to select a small number of places, perhaps only one at a time, where we can try to stop logging or at least convince people that we seriously mean that no more logging should be undertaken. So we have to ask, Are there spots that have a lower priority than other spots? This is not compromising in essentials but admitting that we have neither the manpower nor the funds available to offer visible resistance everywhere. Tactical considerations? Sure, but caused by the limitation of resources—as in any protracted warlike situation, except that we are trying to remain strictly nonviolent.

In short, let us be able to join short-range and long-range considerations, and remember that the long-range considerations in no way should diminish our concern for the local in time and space.

Cultural Diversity and the Deep Ecology Movement

The New Cultural Anthropology

Cultural anthropology and the general history of the major families of cultures on Earth reveal vast differences of attitudes, beliefs, assumptions, and premises as well as of individual, social, political, and metaphysical patterns.¹ How deep or basic are these differences? That is an open question. Inevitably, tentative answers require that we also answer questions about what precisely is meant by “deepness” in this context.

Since the 1940s there have been theories about the future of humankind that emphasize the need for continued richness and diversity of human cultures in order to avoid stagnation of human development. Development in terms of biological evolution may take thousands or even millions of years, but the extreme flexibility of human beings may ensure development through deep cultural changes rather than through manifest biological divergence. Such changes may, however, in part depend on the sheer plurality of cultural differences, regardless of their deepness.²

Plurality requires moderation of the contemporary rapid cultural invasion of other cultures, a process we have seen accelerate in the twentieth century. I look on these efforts of moderation as part of the general effort to maintain richness and diversity of life on Earth. At least, in some easily observable ways there is a convergence of cultures rather than diversification. Here, however, we have to take into account the present-day diversification of subcultures—rapidly changing groups of people trying out

This article was written in 1988. It is being published here for the first time.

“new” ways of life in conscious opposition to what is “customary” within a particular culture.

From the very start of the deep ecology movement in the industrial, materially rich societies, an obvious question was raised: are there or have there been cultures with a more ecologically responsible relationship between the human and the nonhuman worlds? In the United States various North American Indian cultures were studied with special care and furnished a clear answer: yes. At the same time, Europeans with a critical attitude toward industrial societies began with renewed interest to study African cultures. Did members of those cultures really work harder? Did they have less time and opportunity for cultural achievements beyond those serving mere survival? Marshall Sahlins answered no. His main work appeared in English under the title *Stone Age Economics* (1972)—an excellent kind of economics. In his opinion, the most *affluent* Stone Age societies were able to support rich cultures.

A new generation of cultural anthropologists grew up in the 1960s with rather ambivalent feelings toward the basic politics of industrial societies. Many of these cultural anthropologists favored new concepts such as “postindustrial society” and “green society” as well as a new conception about “development”: the “underdeveloped versus developed nations” terminology was largely given up as a near-synonym for “poor nonindustrial versus rich industrial nations.” The basic question was raised, How can the poor nations get rid of the kind of poverty that has a negative influence on life quality? How can they develop *without* following the tracks of the rich, consumerist Western nations?

From the point of view of the deep ecology movement, these new vistas were of prime importance. If the majority of human beings tried to live as the average person in the rich industrial societies does, the doomsday prophecies might come true. When we appreciate a manifest cultural difference, do we react in the same manner as when we appreciate a difference between groups of plants or animals? We do not look upon human beings as animals in a zoological garden.

People active in the various life sciences may easily go too far in finding similarities between phenomena in human societies and those in the animal and plant worlds. One has to be clear about the many pitfalls. In the history of ideas the important line of ideas from Protestantism through

Hegel, Marx, and the Frankfurt School has contributed to an acute awareness of this tendency. On the other hand, there is in this thinking a kind of spiritual arrogance that may hide important analogies and counteract the process of identification with life-forms other than one's fellow human beings. In the worst concentration camps of the twentieth century, the conscious efforts of tyrants to educate guards in brutality consisted mainly of teaching them to look upon inmates as animals. "They are only animals!" Brutes should be handled with brutality—they don't understand decency. One must expect that a combining of human cultural diversity with non-human diversity will sometimes elicit deep-seated repugnance. The recent, somewhat confusing debate over E. O. Wilson's sociobiology (1975) illustrates both tendencies, exaggerating similarities or letting repugnance take over.

Julian Huxley, the biologist and leader of UNESCO in the late 1940s, and many others at that time, worked out the hypothesis that in the very long run, cultural diversity and cultural "evolution" will play for the species *Homo sapiens* a role *analogous* to the role of mutations and species variation among nonhuman beings. Cultural evolution has been thought to result in a development much faster than real speciation among nonhuman beings. This is made possible through the extremely loose programming of human beings: their options in life are more varied, "instinctive" determinants are less dominating even if very strong. The term *analogous* is used rather than *similar* because some differences are deep and important.

Deepness of Cultural Differences

If we subsume human cultural diversity under the concept of intrinsically valuable diversity of life-forms, the adjective *deep* is appropriate. Differences in details are not often important. If people in culture *A* must put something on their heads when entering a church, whereas people in culture *B* must take care not to wear anything there, the difference in behavior is not deep. The attitudes toward a church may be very much alike.

What we are mostly concerned about today is the continued existence of deep cultural differences, not just small variations of mores and habits. From the point of view of the science of cultural anthropology, the criterion of deep versus shallow cannot be precise, but the literature of that sci-

ence shows clearly the presence of a distinction between deep and shallow or, rather, between deep and less deep, big and small, essential and nonessential. Classifications of cultures into groups attest to such discriminations.

Scientists are able to describe fairly precisely differences between societies as wholes. Human cultures as wholes are more elusive. Researchers may point to a great manifold of particular differences between cultures, but the characterization of cultures as wholes is an ambitious undertaking with many pitfalls.

It is understandable that efforts to furnish a cultural taxonomy—with species, genera, families, and so on—are scientifically and philosophically doubtful. In any case, some applications of the distinction between deep and less deep are obvious: the cultural differences among Norway, Sweden, and Denmark are less deep than those among England, France, and Germany. Within the territories of Norway and Sweden there was not very long ago, however, a deeply different, extremely decentralized nation and homogeneous culture: that of the Sami people (generally known as Laplanders). Here we have three levels of deepness that are uncontroversial. It is perhaps unfortunate that the term *deep* is used both here and in the expression “deep ecology movement.” There are, however, similarities of connotation: one line of interpretation of “deepness of cultural difference” makes it synonymous with “cultural difference affecting cultural *premises*,” and premises are at stake when we distinguish between deep and nondeep questioning (problematization) within the general ecological movement. The term *premise*, like *presupposition* (Collingwood), is fairly common in cultural anthropology. Furthermore, there is a movement to defend cultures threatened with extinction. Within the movement is an awareness that, other things being equal, a culture more deeply different from others has a priority. The threatened cultures are small and so-called underdeveloped—i.e., not on the (wrong) way to becoming like us. Their resources are “underutilized.” Conflicts are going on all the time between those who will profit from “helping” them on the way to being like us, and those who try—mostly with little effect—to help the minorities who are critical of this “help.” It is a good sign that the term *development* now is more of a dyslogism than a eulogism.

From the point of view of economic growth and consumerism, no-

madic people are a nuisance for the extremely rich nations. The Sami people protested in vain against roads and dams in their Arctic territories in Norway and Sweden. The movements of their reindeer were impeded and their ecologically sustainable ways of living were undermined. Those young people who wish to adapt to the ways of the powerful invaders, for example, to the ways of the Norwegians, should be helped by the invaders, but those who wish for a development, not abandonment, of the Sami people should not be impeded in their efforts.

One way of clarifying the deepness of a cultural difference is to evaluate the success of efforts to translate a culturally significant text in one culture into a text in the vocabulary of another. (For important reasons I avoid discussing translating one language into another.)

The culturally important Greek term *areté* is only by an old convention translated into English by the term *virtue* and into Scandinavian languages even less adequately by *dyd*. The meanings of the Greek term are laboriously explained in footnotes and in special texts about texts. It is hopeless to find a single word or complex expression that would come near to expressing what is conveyed by *areté*. Therefore, it is better to use one and the same inadequate word in every context. Its occurrence *signals* the Greek untranslatable word. The informed reader knows that in the Greek text there is an occurrence of the term *areté*.

Similarly, the Sanskrit term *deva* is translated “god,” but the informed reader knows that this is not a translation in any precise sense but merely a conventional indication that in the text there is an occurrence of *deva*. A ten-word, not entirely inadequate “translation” might be: a power different from that of human, and mostly greater.

When a Bororo utterance is rendered as “I am a parakeet,” the translation is sometimes thought to be adequate. The Bororo clearly have a term designating the sort of bird we call a parakeet. Of course, the English sentence is misleading, except to cultural anthropologists. Many people with severe mental disturbances say “I am Jesus,” and we conventionally consider their statements false in a historical sense. When hearing the sentence “I am a parakeet” (if not asserted by a parakeet!), we similarly tend to reject the statement as false. The cultural anthropologist will try, perhaps through a couple of semesters’ lectures, to convey—still more or less inadequately—*what is meant* by the sentence when uttered by a Bororo. Conclu-

sion: if a translation of one sentence, *A*, into another, *B*, is an adequate translation only if what is meant by *A* within group *C* is conveyed to *B* within group *D*, then there cannot be any translation of the Bororo sentence into English. This holds true even if we write “approximately conveyed” instead of just “conveyed.”

A different criterion of deepness is the extent to which cultural premises differ. It is a common methodological norm within cultural anthropology to try to “understand each culture on the basis of its own premises.” The assertion of such a norm is justified only if the researchers have means to test properly hypotheses of the kind “*x* is a cultural premise of culture *y*.” If premises are articulated systematically, they form sets of more or less *different* fundamental hypotheses and norms. The more the set of premises explicit or implicit in culture *A* differs from the set in culture *B*, the deeper is the difference. This may be a useful criterion, but the fierce conflicts between cultures often concern very special applications of the premises, rather than the premises themselves.

Whatever the reasonable criteria of “deeply different cultures,” there were more than 100 deeply different cultures about the year 1650. Given some of the sets of reasonable criteria, the number would be much greater.

The number of human beings at that time was about 500 million, less than one-tenth of the world’s human population today. One hundred cultures among 500 million means five million for each culture, on the average. The way some cultural anthropologists reckon, we may say that there were more than 100 deeply different cultures with significantly different “premises.”

In about 1650 Scandinavia was inhabited by two deeply different cultures, the Sami and the dominant Scandinavian culture with its three languages—which are, surprisingly enough, classed as major languages in the supremely interesting book *The Languages of the World* by Kenneth Katzner. The Sami language is still used by more than 10,000 people, but the culture is rapidly degenerating under pressure from powerful industrial neighbors. Until recently, such pressure was blatantly coercive; now there is a tendency to listen to a minority in the dominant culture who want the Sami to be offered a high degree of independence. In other areas of the world, such as in the remaining tropical rain forests, the extermination of cultures deeply different from the dominant ones goes on practically unhindered.

If we use language as a criterion of deepness of difference, Katzner's classification includes nineteen families of languages, plus an "independent" category to represent those not easily put into any family. Some families have many members; the American Indian, for example, has more than 1,000, "the vast majority spoken by small tribes numbering a few thousand people or less" (Katzner 1986: 34).

There are some deep differences in cultures corresponding to different American Indian languages spoken in Canada, the United States, Mexico, Central America, and South America. There are, however, by far fewer deeply different cultures in these areas than the number of languages. Sixty-eight languages are listed as Indo-European. From the point of view of an American Indian, these languages would perhaps be found to be similar and so also the corresponding cultures. From the point of view of a Norwegian, they seem to contain considerable differences. I would vote for the existence of more than ten deeply different cultures when we work through the many branches of the family, the Indo-Iranian, Slavic, Celtic, Germanic, and so on. Again, though, without fairly precise criteria for assertions of forms such as "The cultural difference between *A* and *B* is greater than between *A* and *C*," not much is gained from the above reflections.

Enough number games? The main point is to make available for our imagination and appreciation the still considerable number of deep cultural differences. It is also my intention to heighten awareness of the decrease, even extinction, that is going on, especially outside the sphere of big, rich nations, but also inside them through harassment of subcultures deviating "too much" from the establishment. Life is made difficult for people who try to live in an ecologically responsible way, i.e., an ecologically universalizable way—not from malevolence but from sheer friction.

In the words of the cultural anthropologist Fredrik Barth, cultures are mowed down as with bulldozers. This metaphor and many others suggest a widespread similarity of attitude both toward destruction of diversity of cultures and diversity of animals and other kinds of life-forms.³

Cultural Diversity and the Deep Ecology Platform

It is not common to link the movement to protect nonindustrial cultures to the ecology movement. There are, however, good reasons to do so as long as

we do not neglect the obvious great differences between our relations to human cultures and those to any animal or plant culture (or society). In what follows I shall mention some of the areas in which there are obvious analogies or even similarities.

In the eight-point deep ecology platform proposed in 1984, considerations of diversity of life-forms include diversity of human cultures.⁴ Human cultures constitute complex forms of life on the planet. Or, less dogmatically formulated, the way supporters of the deep ecology movement conceive the *diversity* of cultures is in certain ways very much like the way they conceive the *diversity* of plants and animals and human beings. This justifies mentioning deep cultural differences in point 2.

Point 3 emphasizes that the rich nations with great coercive power have no right to reduce the diversity of cultures with less power, less ability to survive invasion—whether territorial, technical, economic, or cultural. Here it should be added that a lot of this reduction is not intentional, and, as in the case of most invasions, there are fifth columns eagerly supporting the invasion. Furthermore, reduction of cultural diversity is carried out within the poor nations, with powerful tribes or groups suppressing “weaker” cultures.

Point 4 puts forward the contention that the flourishing of human cultures is compatible with a “substantial decrease” of the human population. *Just to provoke*, I have sometimes suggested 100 million as “sufficient.”⁵ With one million as the average membership of a culture, this only provides for a maximum of 100 deeply different cultures. The main point, however, is that there are no vital needs, no ultimate goals that require a gigantic number of people. In a small population the investment per capita would be prohibitive in terms of ensuring broad scientific progress, including progress in mathematical physics and cosmology. Therefore, one would have to think of the future scientific endeavor as a joint enterprise of several deeply different cultures.

The relevance of point 5 of the platform is terribly clear. There are today cases of violent extinction of cultures. More often, there are constant, more or less easily observed pressures from surrounding powerful societies. In *The Careless Technology* (1972), Farvar, Milton, and colleagues describe cases of mindless introduction of Western technology. The ideology of “progress,” Western style, is still used when cultures are invaded. Tourism is permitted

to take forms clearly destructive of cultures. One must admit that it is sometimes very difficult to find out where to draw the line: starving children must be helped even if most kinds of help so far have undermined the culture.

Some serious students of the problems have given up hope that certain cultures can be saved. To support the forces that try to prolong their lives may be brutal toward young people who should learn new things required when their culture gets closer to death. There are no easy solutions to these problems. I just mention them here.

Point 6 was written primarily with the rich countries in mind. To prevent what is generally called neocolonialism, many of the same changes are necessary that are also necessary to protect nonhuman life on the planet. It must be conceded by the rich that efforts to protect East Africa's fabulous fauna were more energetic and better administered than efforts to protect its cultures. Norms announcing that human beings have special obligations toward their own kind were violated, as were norms expressing concern about extreme poverty and about cultural diversity. The situation is different now. The World Wildlife Fund successfully combines concern for people and animals, to mention an example. Much remains to be done, though, to clarify the ethical questions involved and to find tenable solutions.

Point 7 was also written primarily with the rich countries in mind, but if the reports about the lifestyles of the power elites in the poor countries are fair, the situation is precarious there also. Ecologically universalizable lifestyles must be the norm for all groups, including those in the poor countries.

Point 8 is particularly relevant in a time of mass tourism and worldwide economic penetrations. Millions of people who are not trained to contact vulnerable cultures visit them and cause the young to get the impression of an easy life without any obligations, and an opportunity to roam around at will. In all cultures the young are under at least some pressure to conform and to learn a profession. Foreign tourists seem to come from countries without any restrictions except those imposed by the police.

Economic forces operate largely without restrictions, penetrating more or less helpless countries ruled by power elites profiting from foreign domination. Those who essentially agree to the descriptive and normative views outlined have, according to point 8, an obligation to try to assist the implementation of the necessary changes.

The above survey of the Eight Points has not considered "richness" of cultures. The intended concept of richness as applied to the animal and plant world implies, for example, not only preservation of species but also the wide distribution of habitats of the species and the multiplicity of individuals. If we map out bioregions and, in general, different areas of the biosphere, the questions posed are mainly, Have the population and distribution of such and such species diminished in this area? Why? Can we restore these areas?

With cultures, such questions are less applicable. The members of a culture may, of course, belong to a large set of tribes and the tribes will, if nomadic, spread out geographically. At any minor place there cannot easily be large numbers of members of deeply different cultures. Members may come together at big trade centers (Fredrik Barth) and live together at the center without much conflict, but in general, different cultures occupy different territories.

This brings up the large question of the relation of minorities and subcultures to a main culture, and the pseudo-richness of cultures within the borders of a metropolitan area like Los Angeles. Is there a South Korean culture within Los Angeles? The answer, as I see it, is a clear no, although there is a cultural minority and a subculture within the cultural unity of the United States.

Is it ethically legitimate to support minorities in foreign cultures? Must we either support dominant tendencies or try to keep neutral? A philosophy of compassion makes it difficult not to lament the vast amount of suffering in nature. When we contemplate cultures in their splendid diversity and their accomplishments, the same philosophy makes it doubly difficult not to lament the sufferings and indignities manifested there. It is scarcely possible not to utter "How unnecessary, how meaningless!"

The anthropologist and historian offer explanations, trying to show that the vast suffering has been unavoidable. It remains a painful side of human development, but it does not diminish the appreciation of the deep diversity and the great accomplishment under difficult circumstances. Lamentation is a passive emotion in the terminology of Spinoza. Self-preservation makes us try out an active attitude in regard to extreme prolonged suffering in animals as well as in the cultural context, in spite of our limited ability to foresee the overall and the long-term consequences of our actions.

Some cultures, like that of the Chiricahua Apache, are conventionally looked down upon because their technology is “ridiculously” simple and their institutions astonishingly undeveloped. What is mostly forgotten is the great achievement of *a culture shared by practically all adult members*. They are competent in practically every culturally important activity. There are no occupational secrets, no carefully cultivated specialties, no hierarchical structures that leave some members out in the cold; there are no second-rate citizens. The culture as a whole is alive, whereas with us the whole is merely an abstraction, nothing experienced by anyone. It is in deep contrast to conditions in our giant industrial society where we can do practically nothing worthwhile culturally without the clear knowledge of others doing it professionally and much “better.” With us there are no cultural generalists, whereas in the Fourth World cultures there are few specialists. There is simplicity of means combined with an astonishing richness of ends. So it is wise not to look down upon them! They have their shortcomings, we have ours, but ours generate tremendous global impacts.

Concluding Remarks

The movement in the rich countries to protect against their own destructive influence on nonindustrial countries, and therefore on cultural diversity in general, strengthened remarkably in the same years that the deep ecology movement strengthened. Whereas the latter movement depends heavily on grassroots support, people in general rightly feel that they cannot so easily demonstrate their willingness to change the current rapid deterioration, for example, of the conditions of the tropical rain-forest cultures.

Nevertheless, there is some overlap between the two movements. If we look at the efforts within the three great contemporary movements that demand strong grassroots participation—the peace, social justice, and deep ecology movements—the strength of the movement to protect cultural diversity depends on all three.

Deep Ecology and Conservation Biology

In the late 1960s and early 1970s, many of us believed that most ecologists would concentrate on research clearly related to the solution of the ecological crisis. At the universities, however, the atmosphere encouraged “pure” research—research without definite, practical goals. Moreover, those who get jobs within the range of interest of big corporations work with goals in mind but rarely focus on the crisis and rarely “go public.”

Most high-level papers in ecological journals are extremely specialized and only remotely relevant for critical issues. In the early 1970s, those who focus on the general crisis warned supporters of the deep ecology movement not to expect much help from established researchers in scientific ecology.

Then came conservation biology! It started as scientists and managers from many quarters realized that they profited by working together to combine theory with practice in their efforts to save the planet from further destruction. They were in a sense practitioners of ecology. They came from “biogeography, systematics, genetics, evolution, epidemiology, sociobiology, forestry, fisheries, wildlife biology, and the auxiliary sciences of agronomy, veterinary science, resource economics and policy, ethnobiology, and environmental ethics” (Soulé 1986: 5).

Conservation biology is a movement. “The idea of conservation biology seems to convey several things at once, including scholarship, a common purpose, and the potential for making a significant personal contribution to the world. For students and established scientists alike, conservation biol-

This article was reprinted with permission from *Earth First! Journal* (March 20, 1990): 29.

ogy seems to represent a community of commitment, and something of value to identify with" (Soulé 1986: 5). "Consensus can also define a discipline. Disciplines are not logical constructs; they are social crystallizations which occur when a group of people agree that association and discourse serve their interests. Conservation biology began when a critical mass of people agreed that they were conservation biologists. There is something very socialized very human about this realization" (ibid., p. 3).

Insofar as conservation biology is a scientific discipline, it is a crisis science like AIDS and cancer research. That is, it uses certain goals and values as axioms. The intrinsic value of diversity of life-forms and the meaningfulness of a struggle to save life-forms from extinction are taken for granted. Conservation biology is therefore not purely descriptive; it is "a prescriptive science" (Norton-Griffiths, in Sinclair and Norton-Griffiths 1979: 237). Consequently, it is activist-oriented and personal: "The planetary tragedy is also a personal tragedy to those scientists who feel compelled to devote themselves to the rescue effort" (Soulé 1986: 11).

Despite conservation biologists' intense commitments to rescue the nonhuman world, they see the precarious situation of millions of people. "For example, the implementation of 'biosphere reserves' as sites for the harmonious coexistence for humans and nature (UNESCO-UNEP, 1984) depends on both a good grasp of the local biology and on the enthusiastic support of the indigenous peoples. In fact, the survival of many natural biological communities is going to require the creative cooperation of biologists, social scientists, and politicians, especially in the tropics. It won't be long before many conservation biologists are spending more time at community meetings than in the field or laboratory" (ibid.).

From all this it is clear that members of the conservation biology community are supporters of the deep ecology movement—provided that movement is characterized along the lines of the Eight Points of the Naess-Sessions platform. On the other hand, very few deep ecology supporters can boast of being conservation biologists. Many supporters may be ignorant of conservation biology. They may be local activists trying to save a small forest, say, in India.

Some supporters of the deep ecology movement are active in the efforts to save the cultures of nonindustrialized communities. The slogan "Wilderness for the people" attests to the goal of letting people in who do not de-

stroy or degrade wilderness and letting people who already are there remain. It is sad that some Third World authors feel that “American deep ecology” threatens to save spectacular animals at the expense of human beings. It must be clearly stated that the average lifestyle in the United States is such that wilderness and the American way of life are incompatible. The fight to save what remains of U.S. wilderness does not teach anybody how to save Third World wilderness. Conservation biologists in the Third World try to preserve wilderness, but in cooperation with people who determine policies.

Conservation biologists “go public.” That is, they try to make people aware of the perilous state of affairs. Here they part from the main body of earth scientists, who tend to avoid propagating their strong views—if they have any—in public. Why do most scientists avoid voicing strong views? I have made a tentative list of reasons:

1. Time taken away from professional work.
2. Consequent adverse effects on promotion and status.
3. Feeling of insufficient competence outside their area of “expertise.”
4. Lack of training in the use of mass media and in facing nonacademic audiences.
5. Negative attitude toward expressing “subjective” opinions and valuations, or violating norms of “objectivity”; reluctance to enter controversial issues.
6. Fear that colleagues or bosses will think they dabble in irrelevant controversial fields and go public for glory or publicity.
7. Fear of fellow researchers, institutional personnel or administrations; fear of the stigma “unscientific” (ibid., p. 513).

One of the dangers common to the two movements is elitism. It “lurks whenever a field has a strong academic foothold. Whether the root of elitism is arrogance from within the ivory tower or fear from without, it is always a danger. There is no hiding the fact that much of the current interest in conservation biology is occurring within academic circles” (ibid., p. 5). The deep ecology movement faces a danger of being too closely associated with the small group of deep ecology theorists, thereby obstructing the insight that the overwhelming mass of supporters do not publish papers or speak over the radio. These supporters form the backbone of the move-

ment. Their commitment manifests itself in the direct actions going on all over the world. We need the activism of millions of people with the basic attitude of supporters of the movement.

The two movements have another danger in common, "isolation—elitism's child." We should seek contact with groups competing with us in making an impact on the public, avoiding false pretensions and sectarianism. Some supporters of the deep ecology movement, like myself, are professional philosophers and theoreticians. We ask about the ultimate premises of sayings such as "Every living creature has intrinsic (or internal) value (or worth)." We may ask, Why is it so and what exactly does it mean? What does it mean that we do something for its own sake, and why should we do it? What is the relation of Aldo Leopold's criterion in his *Sand County Almanac* (1966)—"A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community"—to general ethics, for example, dealing with friends stuck in the mud or babies starving? Answers differ. According to supporters who are not inclined to ask such questions, nothing much comes out of philosophical speculation. Nevertheless, the unphilosophically minded, as much as the professors, somehow assume when acting in grave conflicts that their decisions are compatible with an ultimate basis, whether religious or otherwise. We assume some kind of "ecosophy," some kind of wisdom, which we are able to verbalize only imperfectly and fragmentarily. (A recent attempt to verbalize such wisdom is offered in Alan Drengson's *Beyond Environmental Crisis* [1989].)

Whatever happens in the years to come, one may expect conservation biology, as a distinguished "mission oriented crisis discipline," to inform us of great successes as well as great failures. Let us hope the former will color the news!

Letter Sent October 1971 to the King of Nepal

Great mountains have since remote antiquity been the object of religious cults. They have been symbols of the highest, the sublime, the perfect, the imperishable, the unsurpassable and unreachable. And of course, symbols of deity.

Those who look upon the great mountains as temples may not hesitate to climb them, only they do it with an attitude acceptable in or on a temple. But to those who rather feel them as symbols of the highest and the unreachable and who reject climbing the summits: it only shows the vanity and impudence and also dullness of mankind to carry out an act symbolizing the dethronement of God and the conquest of the unreachable.

I have belonged to the former group, thinking of mountains as temples and symbols of what is both good and greater than man. Like many others I have spoiled a lot of mountains that could have remained unclimbed, undesecrated.

On behalf of a large section of mountaineers I beseech your Majesty to declare some of your still unclimbed mountains to be holy and not to be climbed.

One of the most holy mountains still left in your country is Gauri Shankar. I propose that the whole mountain be declared holy and untouchable, or its upper parts, let us say above 6,700 meters. The summit is 7,143 meters.

There are, of course, other mountains that in deference to a widespread attitude all over the world should be declared out of reach. In this letter I

This letter first appeared in *The Autobiography of a Shipping Man*, edited by Earling D. Naess (Colchester, England: Seatrade Publications, 1977), 252–53.

DEEP ECOLOGY PRACTICES

speak of Gauri Shankar because a group of Norwegian climbers and philosophers have wished to stay on the slopes and precipices of Gauri Shankar, combining veneration of that great mountain with climbing and enjoyment of its surroundings.¹

We make up only one of the many groups that try to change the attitude of highly industrialized societies toward nature. Climbing as a kind of conquest and subjection of mountains under the power of man belongs to the sick ideas of people out of touch with nature. It was a great moment when Sherpas and others from your part of the world asked that the highest points on certain peaks should remain untouched. But the rapidly diminishing number of untouched great mountains in the Himalayas, as well as in other parts of the world, has shown that their requests have been all too modest. It is time now, in the international year of nature preservation, to make bold steps forward before it is too late.

Most respectfully,
Arne Naess

Migration and Ecological Unsustainability

Before entering the discussion of migration, I shall mention a sort of emigration that is uncommon, but of increasing importance. There is a movement of emigration that roughly may be described as follows.

People from the rich, consumerist countries emigrate to poor countries and settle down for life. They live a rich life using simple means compared to what they did before leaving their native country, and certainly using simpler means than the rich in the poor countries. They and their children adapt to the new culture to an extent sufficient to enjoy good and close relations with the local people.

This kind of rich-to-poor emigration does not involve many people but is a highly instructive subject for research and not completely without influence both in the rich and in the poor countries. In the rich countries the influence is in part due to the fairly large literature created by the emigrants and by the work of social scientists and analysts.

There is also a movement from poor to rich and back. In this case the emigrants return to their own country after some years away, traveling once or several times, continuing to live in harmony with the same principles. Both migrations favor reduction of unsustainability.

Ecological unsustainability in the richest countries is still increasing. In 1983 *The World Conservation Strategy* pictured an equation: on the left-hand side was one man, a Dane; on the right-hand side were forty Somalis. The meaning: during the lifetime of one member of a rich industrial state, he interferes as much with the ecosystems of the planet as do about forty Somalis. Each of the children of one young Somali who emigrates to Den-

This article was written in 1993. It is being published here for the first time.

mark interferes forty times as much as they would have done if this young Somali had stayed at “home”—if we presume he had a sort of home. The unsustainability in his new home increases. Perhaps, though, people in the rich countries could learn from immigrants to downscale consumption? Unfortunately, the outlook for this is very bad, and not much can be expected in the near future. What happens is that because children of immigrants have low-paid jobs, they do not quite reach the average consumerism level.

From an ecological point of view, it is convenient to distinguish the three cases, the settling and movement of individuals from one of high unsustainability increase to one of low unsustainability increase, and the opposite, and that relating to roughly equal status. If the movement does not stretch over generations, the negative effects of the poor-to-rich movements are less serious, because the adoption of the consumerist lifestyle often is incomplete during the first generation. Children of immigrants adapt more closely to the established norms.

Let us approach the ethical aspect of immigration, and tentatively distinguish three categories of immigrants from poor to rich countries. The first contains migrants who *prefer* to live in country *A* rather than *B*, perhaps love, wish, and long to live in *A* rather than *B*, most often for economic reasons.

The second category equates to “refugees” according to more or less international criteria. Most of them are classed as refugees for political or religious reasons. They often maintain that there is a fair chance that they will be imprisoned or otherwise seriously discriminated against if they remain in their home countries. Hundreds of millions of people live where nobody can be sure that he will not suddenly be imprisoned or shot, even if he does not belong to organizations trying to overturn the government, even if he does not criticize the established order.

In what follows I focus on those refugees whose intention it is to *remain indefinitely* in the new country. At the moment (1993), conditions in former Yugoslavia are such that there is a great need for temporary emigration, but not to leave their communities for good. I am not talking about them as immigrants in the new country.

The third category contains two very different groups: the desperately needy from a material point of view, and members of the active political

and social nonviolent opposition to brutal authoritarian regimes. They are regularly imprisoned, tortured, or killed, and their families are threatened in a most infamous way.

The weight of purely ecological considerations seems to me indisputable only when applied to the first category. Any responsible ecological policy will discourage or tend to minimize migration of the first kind. The two great goals, reduction of total consumption and reduction of population, become more difficult to reach. The economic pressure to maintain or even increase private per capita consumption is so strong, in part because it is believed to be the decisive means to reduce unemployment, that reduction of population must be seriously considered.

It takes strong nerves to live under brutal authoritarianism without serious loss of life quality. It shows ethical strength when people aware of the increasing ecological unsustainability nevertheless insist that rich countries ought to accept more immigrants of the second category. How can we reject unfortunate people *knocking at our door*? Apart from the ethical argument, it has been (seriously?) suggested that if a hundred million people from the poor world settled in the rich, the per capita consumption might decrease even if the governments desperately tried to keep it up. If what is maintained in the following is tenable, a gigantic poor-to-rich-country migration does not solve any major problems.

The third category of people live under conditions materially so terrible or so dangerous that they must be accorded the highest priority. The desperately needy are mostly not able to reach our airports or even our borders. Many are in a condition that precludes even being transported to our countries, but there are also many families who would stand transportation and who would with great certainty be helped out of a status of *extreme suffering*. As I see it, they must be accorded a priority over people who are having a bad time, who certainly suffer, but are not in a state which we cannot but assume is truly terrifying.

The same level of priority must, as I see it, be accorded the active opposition and their families, people who courageously risk their lives fighting some of the causes of the miserable state of affairs in a large number of countries.

Not very long ago, it was fairly generally accepted as a good and important thing to hand out some money to beggars. Their need was so obvi-

ous and so near. Then came a period of reflection: the community must try to help in a way less arbitrary than by handouts to people able and willing to ask for small coins. Today, I think we have to consider how we can best decrease extreme suffering, whether the victims are able to knock on our doors or not.

A similar need for reflection makes itself felt when we assess the urgency of stopping the increase of ecological unsustainability. It has to do with “discounting” the future, the ethical abnormality of not taking seriously the life conditions of our children and grandchildren, pushing problems over to them—and doing this in spite of the insight that if we continue to support irresponsible policies, the problem of reaching sustainability will only become much greater. We refuse to carry a small load, thereby making it necessary for the next generations to carry a very much larger one.

The Third World countries suffer from migrations on a scale unknown in the rich countries. That from Bangladesh to India some years ago is a case in point. The rich countries have the means to help in such cases, but they do practically nothing. They could, for example, help solve the housing and school problems. Applying the cost-benefit criterion, one can do more for more people in that way than by putting Third World people in a rich country. Thus, the ethical question has a solution. It requires, however, that geographical distance be taken less seriously and that the increasing ecological unsustainability be taken more seriously. To help the Third World with its formidable migration problems provides us with the opportunity to help people increase their quality of life from a very low level to a significantly higher one while remaining within a culture in which they can feel at home, and feel competent and adequate.

Why do we have to give the people who must be assumed to be in a state of extreme suffering the highest priority? Why can we not just say that suffering is suffering? Why actively search for the worst cases, which presumably will require much work and an intolerable amount of arbitrariness? As to the latter, immigration officers already face that problem in assessing applications from people of the first and second categories. Active search may decrease arbitrariness, because those who are picked out are primarily those whose conditions *without doubt* are extreme.

The first question leads inevitably to the philosophical *problématique* of intensities versus quantities. (If we add warm water to a bathtub contain-

ing warm water, this will not make the water hot. Temperature is an intensity. Addition does not count.)

Suppose we are in a position *either* to relieve one human being of a moderate pain *or* to relieve another human being suffering an evidently stronger or more intense pain. If other relevant conditions are equal, we naturally focus on the one with the more intense pain. Suppose, however, that we are in a position to relieve either ten people of a moderate pain or one person of a more intense pain. What would we do? We assume that the case clearly permits a comparison of the degrees of pain. If we decide to relieve the one suffering intensively, we follow what we may call the principle of intensity applied to pain. It is necessary here to use *pain* in the sense of *felt* pain. We are concerned with feelings. *Felt* pain has intensities, and the calculus of adding and subtracting quantities of pained people does not apply. That is, when two people are in pain, that does not create a greater or more intense pain. (What about mutual influence? It changes feelings. Yes, but consideration of such influences belongs to the assessment of causes and effects of the felt feeling, not to the felt feeling itself.)

If by chance 1,000 people each sit down on a sharp nail (independent of one another and assuming for the sake of simplicity that there is a definite standard of pain associated with sitting down like that, and also a common pain threshold), no terrible pain is created. No pain a thousand times stronger, or even just a little more intense, emerges. That is, there is no stronger pain than if only one person at that moment had sat down on a nail. Because it is often difficult and resource-consuming to conclude rationally who suffers the worst among people we are in a position to help, we tend to let numbers decide. Often, we are *not* confronted with excessive difficulties. The same holds for assessing the graveness of threats involving clear risk of extreme suffering. A freedom fighter under some of the cruel regimes risks torture all the time, repeated torture until he breaks down definitively or dies. That is *evidently* a much more severe threat than the threat experienced by the average citizen of the country.

When we have to decide which categories of refugees to help, the principle of intensity may be applied without great arbitrariness. There are a multitude of people who are more or less helpless and who with great certainty can be understood to suffer greatly. The conditions in certain Third (and Fourth) World countries are such that, in my opinion, we in many

cases have to give them priority. Typically they are people with no formal education, often old and attached to big families. They adapt only with great difficulties to conditions in the rich countries. They must be helped where they are, in their own countries. Many young people in the rich countries are willing to help by spending a few years in a poor country, but then they must be assured that they get jobs when they return home.

Experience tells us that foreign aid rarely manages to reach satisfactorily those who need it. This owes to some extent to the low priority given to the organization of the aid. When high priority, including appropriate education of people sent into the country, is afforded, and no war going on, the aid is not less effectively distributed than aid in one's own country. Foreign aid must be increased, not decreased.

If these guidelines are followed would there be less migration from poor to rich countries? Not necessarily, and not in some cases—for example, Norway and Sweden. Norway experienced what it meant to live under a tyrannical government during the Nazi occupation of 1940–45. People who worked in the resistance movement against the occupiers could be helped to escape to Sweden or Great Britain when in great danger of being caught by the Gestapo. Appropriate secret organizations saw to that. Thousands escaped concentration camps and repeated systematic torture. Nobody could be sure that, under torture, he or she would be able to keep silent about things the Gestapo wanted to know. Escape was important for the “homefront.” Sweden was aware of the value of its help. What I am driving at is the paramount importance for freedom fighters in countries not just mistreating people but using systematic torture, to know that organized escape routes exist to other countries. Norway and some other countries might organize escape routes, receiving freedom fighters in grave peril and their threatened family members. This would be a kind of *active* immigration policy.

The tyrannical governments would not like this “emigration.” They would protest vigorously, but to no avail. Information about freedom fighters in grave danger can be obtained through normal international channels. Amnesty International provides one of them. Amnesty International must not get into trouble. Therefore, it can only do what it always has done: keep its files open for those who need information. What I propose is simply a more active refugee policy for a category of people who desperately need to

leave their country for good or for a time. It is at the same time a demonstration against torture, which many of us consider ethically to be on a more sinister level than straight killing of opponents. Torture is a fundamental attack on human dignity.

A main philosophical basis of the above proposal is, in my opinion, to be found in the acceptance of the intensity principle and some of its limited consequences of relevance to the immigration policies of the rich countries. I would find it of considerable value to get the proposal widely discussed.

Philosophy of Wolf Policies I: General Principles and Preliminary Exploration of Selected Norms

Coauthored with Ivar Mysterud

We, as philosopher and biologist, here present some preliminary explorations of values and norms of importance in the wolf-human relationship. The presentation is centered on problems as we see them from the modern wolf range in Norway, where there *should* be a mixed community of sheep, wolves, and human beings. At present we have 3.2 million sheep, 4.1 million human beings, and 5–10 wolves. The wolves are confined to a small area containing small scattered sheep farms. The owners, with local approval, do not accept the wolves. What norms should be considered in the process of changing this wolf/sheep ratio slightly in favor of wolves? How can we work today for a viable population of wolves? This article presents some general principles and philosophical methods for discussion in the spheres of ethical attitudes and opinions in norm conflicts concerning wolves. Important is an understanding of the logical priority of the normative system, and the need for it in a systematic analysis. This should be used extensively as an analytic tool in the many intricate problems of wolf management, some of which go all the way down to the rock bottom of philosophy and political ideology.

Wolves (*Canis lupus*) and human beings are carnivores, and domestic sheep (*Ovis aries*) are food for both of them. Depredation of sheep might therefore be interpreted as competition for food between wolves and human

This article was reprinted with permission from *Conservation Biology* (Oxford: Blackwell Publishing) 1 (May 1987): 22–34.

beings. The raising of sheep, however, is also economics for the sheepholder, who in Norway is part of a farming culture that has traditionally invested in bounties to get rid of wolves. Other groups identifying with trends in modern industrial culture invest money in the opposite, to experience and enjoy wolves. A collision of subcultures?

The wolf is today nominally protected by law in Norway and Sweden. Nevertheless, what man should and should not do to sheep and wolves is a grave question that illustrates well the problems of letting large predators live in sparsely populated areas. The problems are at present under intense debate.

The debate goes all the way down to the rock-bottom problems of philosophy and political ideology. The practical solutions to the so-called wolf problem reveal philosophical premises as much as they reflect concrete economic and other mundane interests. Philosophical research attempts to codify our deepest and most comprehensive attitudes and beliefs. This philosophical aspect is essential when we try to codify our attitudes toward nonhuman living beings. We recognize a "wolf problem" as well as a "human problem."

"Live and Let Live!" Inescapable Identification

The basic development of human behavior patterns seems to have provided us with an inescapable feeling of kinship with all living beings, but only if our culture, society, or group membership does not actively inhibit this feeling. From an early age we "identify" and perceive ourselves in something else.¹ The proposition that we only perceive *similarity* with other kinds of living beings is based on a misunderstanding. The spontaneous experience of relatedness is better expressed by the term *sameness*; that is, *identity*. It is, of course, an identity with awesome differences: we can change our attention and immediately be aware of profound differences. One's dog is vastly different from oneself, but we intuitively identify strongly with it as "a member of the family."

One of the most compelling cases of identification is furnished by our awareness of suffering. Even if we do not think that plants suffer, plants have traits that we spontaneously perceive as symptomatic of imperfect

conditions of well-being. We actually see them suffer from dryness, heat, cold, or lack of nutrition as we see the suffering of human beings.

Identification need not result in love. We may see our own bad characteristics in an animal. Except in people who are well acquainted with them, rats elicit disgust for obvious social reasons. The cultural setting of wolves is similar but formidable in its complexity and variation. Naturalists and mammalogists have “lived with” wolves and followed up with extensive reports.² Not surprisingly, the process of identification has been intense and positive in these cases. So far, however, the general public inside wolf localities has scarcely been influenced by the rapidly increasing prowolf literature.

Even exquisitely “ugly” animals such as the Tasmanian devil (*Sarcophilus ursinus*), which seems to be unflinchingly aggressive toward human beings and completely devoid of gratitude for whatever we do to satisfy its hunger and other needs, elicit sympathy and respect not only when considered *sub specie aeternitatis*, a natural wonder, part of the richness and diversity of life on the planet, but also when regarded as a symbol of our own aggressiveness and lack of gratitude. The Tasmanian devil permits us to laugh at ourselves.

Identification motivates norms of at least partial protection: rules of how to respect the dignity and stature of even an obnoxious animal are similar to our rules of respect for the dignity of murderers in prison. Such norms are, of course, also established through the operation of other motives, but identification must be considered if we are truly to understand both the strength of protective efforts in favor of wolves and the passionate urge to exterminate them.

Mixed Communities with Wolves, Sheep, and Sheep Owners

Sociology distinguishes *Gemeinschaft* (community) from *Gesellschaft* (society). The distinction is somewhat differently defined by different authors. In sociology, “community” is defined in such a way that only human beings are considered members. Concepts of human community are obviously needed, but today broader concepts are also required. We need to break down some of the barriers commonly erected between humankind and other forms of life within our common space. We need a concept of mixed

community, defined in such a way that human beings and *limited groups* of animals that play a more or less well-known role in human affairs are included as members.³

It is unfortunate that the organizational cleavage between the social and natural sciences has made many students of the former seemingly incapable of conceiving mixed communities. Dogs and cats have long been considered sort of members of the family, not quite on par with children and the mentally handicapped, but certainly the subject of privileges and status not accorded people or animals outside the family. The same holds true of sheep, cows, pigs, and other mammals of the same category in traditional herder communities.

The concept of "mixed community" may be seen as a subconcept of a general "life community" embracing all kinds of life. Considering that human beings know about only a microscopic part of the living beings to which they are hosts and even less of those living beings in their nearest environment, human relations with all other members of a "life community" are significantly different from those within mixed communities.

We do not favor the term *life community* because of the abstractness of its relations. We follow ways of thinking conceptualized in phenomenological philosophy. It is presumed that there are conscious relationships between members of a mixed community and an occasional awareness of one another even when there is no physical nearness. This concept of mixed community does not compete with concepts within biology. Plant ecology and animal ecology embrace the collection of species populations in a given space and treat them collectively in the field of community ecology.⁴

For thousands of years the wolf has been part of mixed communities in the Nordic countries. Until this century, the fairly large number of wolves and the limitations of available weapons made wolves a threat. This has totally changed. Furthermore, the deep ecological movement, the recent extensive prowolf literature, and the material richness of Nordic countries have, as an inevitable consequence, influenced the willingness of people outside wolf localities to give wolves a new and better chance to survive.

Here are a few facts about our Norwegian mixed community. At present (1987) we are 4.1 million human beings and 2.3 million sheep on 323,886 square kilometers of land (Spitsbergen and Jan Mayen excluded). Norway is part of the great Fenno-Scandinavian mountain range, and 50

percent of the land area of the country is bedrock. A mere 2.8 percent of the land is cultivated soil, 5 percent is lakes, 20 percent is productive forest, and less than 1 percent is populated. Norway is the country with the second lowest population density in Europe, although it is the fifth largest in terms of area. The human population density is 13.1 inhabitants per square kilometer.

The wolf has been regarded as nearly extinct and is at present directly threatened in Norway. Wolf numbers were estimated at five to ten during the 1960s and 1970s and at fourteen to twenty during the early 1980s.⁵ Today these “Norwegian” animals roam a limited area covering part of Sweden and perhaps part of Finland. Probably five to ten wolves share the Norwegian area with sheep and human beings; this corresponds to a wolf population of fewer than 0.0005 individuals per square kilometer. They kill at present about 400 sheep per year, fewer than 0.2 per thousand of the country’s total sheep stock.

It is paradoxical that this very small sheep loss compared to the total sheep loss and the minute population of wolves has elicited such vigorous debate and socially important plans of action at local and central levels of administration and management. The paradoxical situation can only be explained by searching much wider and deeper than the biology and economics of wolves. It leads us to consider the unique position of wolves within Norwegian and many other cultures.

It is irrelevant that the total number of sheep in Norway is vastly greater than the number of wolves. The same holds true when comparing the number of sheep killed by wolves with the large number of sheep that die or disappear because of inadequate efforts to protect them. What counts is the attitude in local communities within the wolf area. Here people live and support themselves through small-scale agriculture and husbandry. They wish and demand to continue with what they have done for generations. They are not willing to go into agribusiness or any other large-scale business in “safer” areas; they are not interested in living in cities, not eager to acquire power as members of the bureaucracy or by other kinds of “success.” They consider the loss of thousands of sheep from traffic accidents, the sudden onset of winter, and so forth, as inevitable, but the loss of twenty sheep to wolves as easily avoidable. Just kill the wolf! The comparison, though, is not quite fair. If an owner of forty sheep lost twenty in traffic, he

understandably would make a fuss about it and ask for full compensation. The actual situation is that a small-scale sheep owner suddenly loses a considerable part of his herd by wolf attack and the *whole community* is outraged.

“So what?” officials in many countries would say, but Norway is a welfare state and supports a cultural philosophy stressing intense respect for old, local, nonurban communities. Communities that mobilize to fight any policies protecting wolves are in ecologically long-term-sustainable *Homo sapiens* habitats. Northern and western Europe, which suffers increasing ecological destruction through unsustainable development, is an example. These communities exemplify subcultures in danger of being destroyed for reasons not very different from those that are bringing wolves to the verge of extinction: habitat deterioration and shrinkage. That is the awkward situation in the question of wolf policy: respect for wolves, but also respect for old, ecologically unobjectionable human communities.

Wolf Policies Reflect Philosophies as Total Views

A philosophy of the wolf-human relationship must be part of a more general philosophy. How general? *Philo-sofia* is love of wisdom, and wisdom must show up in wise action as implementation of wise decisions. Knowledge is not enough. Decisions, if they are to be wise, must take *everything relevant* into account. Because knowledge of what will be the immediate, not to mention the remote, consequences of an action is limited, the decision will be made on the basis of uncertain premises of very different kinds. Therefore *in principle* the premises of any decision are *all-embracing*. In wolf-human philosophy we neglect astronomy and astrology, implicitly asserting the first irrelevant and the second perhaps a more complicated verdict. We cannot neglect politics, and politics is from a cognitive (knowledge- and acquaintance-related) point of view based on a political philosophy. An example concerns the justification of a central government or a national majority decision to make illegal the shooting of wolves by locals. Hypotheses in sociology, psychology, and cultural anthropology are clearly relevant.⁶ They concern our decisions, and are expressed here by sentences ending with a period. A philosophy is needed that connects the hypotheses with norms—sentences ending not with a period but with an exclamation mark. We believe that the normative aspect of the basis of wolf policies

needs more comprehensive and clear articulation. We shall, therefore, be somewhat pedantic in our use of exclamation marks.

It is a common notion that every animal, however fierce and destructive, has a place in the whole of nature (Naess 1985a: 68–76). The notion is especially forceful when we talk about the larger ones and not “animals” such as bacteria. The idea that each species of animal has a place in nature has a strong implicit normative aspect. We might reformulate and express this in many ways: “Every kind of animal rightfully possesses a place in the whole!” “Mankind cannot violate this right!” “However, we may defend ourselves against attacks and hunt for purposes of food and clothing!”

Empirical studies suggest that such a normative view is prevalent in Norway, and we guess it prevails in many other countries as well. This should be taken into account when planning controversial conservation measures.

The view clearly applies to wolves, but it does not automatically apply to wolves in every particular region, say, in Norway. People know that there are plenty of wolves in other countries, for example, in the Soviet Union. There is no question of global extinction of the species. However, there is an awareness that wolves have, until the twentieth century, been common in Norway. They “belonged” there, but there were no norms discouraging killing, no limitation of the right to kill on sight. Today we think one may say that the prevalent, if unformulated, view is that the wolf is not only a genuine part of Norwegian nature but a genuine part of mixed communities.

No empirical studies have been done about this, and, unfortunately, such studies of opinions about wolves in Norway have little chance of revealing genuine attitudes. Those for or against wolf protection seek principally to influence government policy one way or another. Opinions are “mobilized” as in wartime. The general philosophical and ethical attitude in favor of having a viable population of wolves in Norway is strong, but so is that of people concerned with protecting their livestock and economy. The resulting norm conflict is common in other countries,⁷ but the long-range concern has, for simple reasons, not been clearly or repeatedly formulated in the conflict.

To what extent *should* prejudices, unreasonable fear, and cultural stereotypes of wolves be taken into account in policy decisions? A direct answer will properly end with an exclamation mark: “We *should* do such and such!” Are we really in a position to judge the threat to children, for ex-

ample, from immature wolves straying near settlements? A direct answer may end with a period: "No." This is a *hypothesis* in the form of a negation, but is the direct answer certain enough to *justify* our including it in a research report? Direct answer: "No!"
